CERTIFICATE

This is to *certify* that the Research Thesis entitled “**Studies on Stability Assessment of Large Caverns in Himalayan Region**” submitted by **Sripad Ramachandra Naik** (Register Number: **090700MN09P02**) as the record of the research work carried out by him, is *accepted as the Research Thesis submission* in partial fulfilment of the requirements for the award of degree of **Doctor of Philosophy**.

Prof. V.R. Sastry

Department of Mining Engineering,
(Research Supervisor)

Chairman – DRPC
Department of Mining Engineering

Dedicated to
MY BELOVED PARENTS

Smt. Susheela

and

Sri. Ramachandra K Naik

ACKNOWLEDGEMENT

First of all, I am extremely grateful to my research supervisor, Prof. V. R. Sastry, Department of Mining Engineering, NITK, Surathkal for his excellent guidance, continuous support and inspiration throughout this research work. His deep insights helped me at various stages of my research and I remain indebted for his invaluable support at all time.

I express my sincere gratitude to RPAC members, Prof. A. Vittal Hegde, Department of Applied Mechanics and Prof. K. Narayana Prabhu, Department of Metallurgy for their critical assessment and very valuable suggestions during the progress of my research.

I am thankful to Prof. V R Sastry, Head, Department of Mining Engineering and Chairman DRPC, Prof. M Govinda Raj, Dr. M Aruna, Dr. Harsha Vardhan, former Heads of the Department of Mining Engineering, for their continuous support and encouragement during my research work.

My thanks are due to all professors at Department of Mining Engineering for offering very innovative subjects during the course work and I also thank other supporting staff for their timely help and support. I thank Mr. Raghu Chandra, Mr. Nagesha and other research scholars for their support.

I am extremely grateful to my institute, National Institute of Rock Mechanics (NIRM), Bengaluru for allowing me to take up this research work and permit me to use all the resources at the institute during my research work. I am thankful to Shri. C Sivakumar Director (Additional Charge), NIRM for his persistent encouragement and support for my PhD work. I also fondly remember the encouragement and support received from my former Directors, Dr.V Venkateswarlu, Dr. P.C. Nawani and Prof. R. N. Gupta and I am grateful to them.

I would like to place my sincere appreciation on record to the management of Tala Project, Bhutan for providing all logistic supports and help during the research work in the field. I am thankful to my colleague Mr. K. Sudhakar for his untiring efforts in

assisting me during the field investigations. I am also thankful to my other colleagues Mr. Aditya Mishra, Mr. Vijay Sekar and Dr. Rabi Bhusan for their help during numerical modelling studies and analysis of the data. I also appreciate the encouragement and support received from all my colleagues at NIRM.

My special appreciation is to my wife Padmavati and my little daughter Tanushri for their unconditional support and affection during my research work. I am also indebted to my parents Smt. Susheela and Sri. Ramachandra K Naik for their constant support. I also appreciate the encouragement received from my brother, sister and my in-laws.

Finally, I am thankful to everyone who helped me directly or indirectly during my research.

Sripad Ramachandra Naik

ABSTRACT

“Studies on Stability Assessment of Large Caverns in Himalayan Region” is a research study carried out to understand the behavior of large caverns in Himalayas, where rock mass is generally unfavorable for tunneling. Caverns at Tala hydroelectric project, Bhutan, situated in lower Himalayas were chosen for the study. The prime objective was to study the rock mass behavior at various stages of excavation of large caverns. Field studies were carried out to measure various parameters like, displacement, wall convergence, load on the rock bolts, load on steel ribs and strains in the rock bolt using magnetic ring multipoint borehole extensometers(MRMPBX), total station, reflective targets, load cells and instrumented bolts. 3D numerical modelling studies were carried out using continuum (FLAC-3D).

Analysis of MRMPBX data in the crown of powerhouse cavern indicated significant influence of side slashing in the crown (accounted for 71-88% of total displacement) on the stability of the crown and super incumbent rock mass. There was clear indication of joint separation taking place even upto 10m above the crown, indicating the requirement of long rock bolts of minimum 12m length. Strains calculated in the crown at some places were more than 1%. Steel ribs installed in the crown also recorded more than 100t load. Benches within one time the width of cavern had maximum influence on the rate of load increase on the steel ribs.

Upstream and downstream wall of powerhouse cavern converged by more than 200-300mm in unit bay area and 135mm in service bay area. Calculated strains during the monitoring period were 0.92 to 1.74% in the unit bay area and upto 0.66% in the service bay area. Analysis of convergence data indicated that about 88% of convergence took place during excavation of caverns and about 12% was recorded during post excavation period. Average convergence rate during excavation of benches varied from 0.56mm/day to 0.67mm/day, whereas convergence rates during other miscellaneous excavations varied from 0.38 to 0.49mm/day. During the post excavation monitoring done for 3 years, convergence of 16-50mm was observed with average convergence rate of 0.021mm/day to 0.063mm/day. Predicted convergence from 3D continuum model compared well with the field monitored values within 15% at most of the places.

3D modelling results indicated maximum strain of 3.34% on the upstream wall and 3.35% on downstream wall for the entire excavation period. On the upstream wall, strains of more than 2% were observed in unit bay area. In the service bay area, strains were restricted upto 2%. On downstream wall maximum strain was observed near the bus ducts. Higher strains were concentrated near the crown of bus ducts. On downstream wall, strains of less than 2% were observed in service bay area. In transformer hall also similar behaviour was observed. Results clearly indicated that when the height of excavation increases (w/h ratio decreases), unit bay area experiences higher strain.

Rock bolts in the walls of powerhouse cavern recorded load upto 45t. Bolts on the upstream wall experienced loads of higher magnitude compared to the bolts on downstream wall. During post excavation, load on the bolts on downstream wall was greater (average 21.4%) than the load on bolts on upstream wall (average 8.7%).

3D modelling results showed higher displacements concentrated near the intersection of floor of the cross tunnels and downstream wall of the powerhouse cavern. In general, there was increase in principal stresses in the crown and reduction in principal stresses in the walls of cavern, which corroborates with high values of convergence recordings in the walls. Tensile stresses were observed in the rock mass, particularly in the floor of powerhouse cavern due to floor heave.

Analysis of stress concentration factors in the pillar between powerhouse and transformer hall indicated factors due to maximum and intermediate principal stresses were almost equal (varied from 1.20 to 1.58). Normal stresses had higher influence on the stress concentration factors in the pillar. Stress concentration factors near the floor of transformer hall upstream wall was maximum and stress relaxation was to a lesser extent compared to other locations.

Strength of the rock mass was estimated using 3D Hoek and Brown failure criterion. Caverns are found to be stable as the strength to stress ratio in the surrounding rock mass was greater than two except for few patches near the walls of the cavern. Tensile failures were noticed in the corners and at the floor of the powerhouse cavern. Monitoring in the cross tunnels indicated development of load in the range of 100-110t in the steel ribs and >35t load on the rock bolts.

Changing the orientation of the cavern with respect to the maximum principal stress direction had maximum effect on the upstream wall of the powerhouse cavern with an increase of maximum displacement by 28.7% at an angle of 90°. Study also showed that maximum stress concentration factor in the pillar due to vertical stress does not change significantly with cavern orientation except in the pillar near the end walls.

When the cavern is oriented parallel to maximum principal stress, maximum stress concentration factors due to vertical stress were the highest on the upstream wall of powerhouse. But at an angle of 90°, confinement provided by horizontal stresses decreased, that could cause instability problems in the wall. Confinement levels provided by horizontal stresses were greater on downstream wall of transformer hall than on the upstream wall of powerhouse cavern.

Sensitivity analysis results clearly indicated that friction angle was the most sensitive parameter among the all considered parameters. Predicted convergence increased by an average of 76.2% when the friction angle was reduced by 20%, and decreased convergence by 33.9% when friction angle was increased by 20%. Thus, the friction angle has very considerable influence on the convergence in the model. Cohesion, elastic modulus and Poisson's ratio were less sensitive in that order.

In this research study, integrated approach involving field investigations during the excavation and post excavation period and 3D modelling followed by correlation between the results. Both the stages of investigations could explain the behaviour of the cavern and surrounding rock mass in a comprehensive manner under a Himalayan geological setup.

Key words: Caverns, Convergence, Displacement, Instrumentation, Monitoring, Principal Stress, Normal Stress, Strain, Numerical Modelling, Strength to Stress Ratio, Instrumented Bolt.

INTRODUCTION

India, home to 18% of the world's population, uses only 6% of the world's primary energy. India has been responsible for almost 10% of the increase in global energy demand since 2000. Its energy demand in this period has almost doubled, pushing the country's share in global demand upto 6% in 2015 from 4.4% at the beginning of the century. However, on a per-capita basis, energy demand in India remains only around one third of the world average, slightly lower than the average for the African continent (Fig. 1.1). Per-capita electricity consumption in India has been continuously increasing over the years. From 734kWh in 2008-09, the per capita consumption has reached 1075kWh in 2015-16, an increase of 46% in 8 years. The per capita consumption has been increasing at an average of 6% every year. India is one of the fastest growing economies in the world. India's economy, already the world's third-largest, is growing rapidly with an impressive economic growth of over 7% per annum.

India's energy consumption has been growing rapidly in the last decade. It stands third with total energy consumption of 882Mtoe after China (3101Mtoe) and United States (2196Mtoe) for the year 2015. Total energy consumption is growing at an average rate of 4.7% per year for 2000-2015 period as shown in Fig. 1.2 (Anon, 2016).

India is committed to produce low-carbon sources of energy, particularly led by renewable energy sources like solar, hydro power and wind power. India's contribution is likely to be the highest in projected rise in global energy demand, around one quarter of the total. However, energy demand per capita in 2040 will be still 40% below the world average. With energy use declining in many developed countries and China entering a much less energy intensive phase in its development, India emerges as a major driving force in global trends, with all modern fuels and technologies playing a part (Anon, 2015).

Coal still dominates the energy demand in India. In 2013, it constituted 44% of total and renewable energy including hydropower, which is just at 2%. Renewable energy in India is mainly through solar, wind and hydropower.

Note: toe = tonnes of oil equivalent.

Fig. 1.1 Per-capita energy consumption in India and selected regions (Anon, 2015)

1.1 HYDROPOWER

Hydropower potential of India is about 1,48,701MW at 60% load factor, one of the largest in the world. India is 7th largest producer of hydroelectric power. Present installed capacity of electricity generation is 303.12GW of which only 15.55% (47.12GW) comes from hydropower. Although capacity has steadily increased, the contribution of hydropower to Indian power generation has been on a declining trend in recent decades, from close to 40% in 1980 to 15.5% in 2016. In India, less than 25MW capacity power plant is termed as small hydro and is classified under renewable energy source along with solar power, bio-power and wind energy and constitutes 9%

of hydropower in the country. Present capacity of 47GW represents a little under a third of the assessed hydro resource and much of the remaining potential is in the north and northeast regions (in the Himalayas). A further 14GW are under construction, although some of these plants have been delayed by technical or environmental problems and public opposition. If developed prudently, hydropower can bring multiple benefits as a flexible source of clean electricity. Fig. 1.3 shows distribution of electricity generation from different sources as on June 2016 (Anon, 2016a, 2016b).

Fig. 1.3 Installed capacity of electricity generation in India (Anon, 2016b)

1.1.1 Hydropower development in Himalayas

Himalayan region offers potential for large hydro projects with water head in excess of 500m available due to the topography and geological setup of the area. Due to high risks of landslides and slope failures, the preferred method of locating the hydropower plant has been in underground caverns. Higher capacity power plants need more space to house the equipment and other facilities for power generation and this calls for creation of large underground caverns.

There are issues specific to hydropower, notably the high levels of sediment in the rivers coming down from the Himalayan mountains, which can reduce reservoir storage capacity and, if not removed, cause heavy damage to turbine blades and other steel structures in a hydropower plant. Projects are delayed beyond their schedules due to unexpected geological surprises and ground control problems.

Another avenue for India to benefit from hydropower is through co-operation with neighbouring countries. India has assisted Bhutan in developing 1.5GW of hydropower with three projects. Ten more hydro projects are in various stages of construction or preparation. Recently, India has approved projects with a combined capacity of 1.8GW with Nepal.

Currently, northern Indian states contribute 43% (18.31GW) of total installed hydro power capacity. Himalayan states of Himachal Pradesh (8%), Jammu and Kashmir (5%) and Uttarakhand (6%) constitute 19% of total hydropower in the country. Himachal Pradesh currently has two major power plants, Nathpa Jhakri hydro power plant (1500MW) and Karcham Wangtoo hydro power plant (1000MW) on river Sutlej. Both these power plants are located in large underground caverns. Other notable hydro power plants with underground caverns in Himachal Pradesh are Chamera-I (540MW), Parbati Stage III (520MW), Chamera-II (300MW), Baspa-II (300MW), Chamera-III (231MW) and Larji (126MW). In Uttarakhand, Tehri hydro power plant (1000MW) is in operation and other project with pumped storage scheme (1000MW) is under construction and both have large underground caverns. Other notable power plants which are situated in underground caverns are Tapovan Vishnugad (520MW), Vishnuprayag (400MW) and Chibro (240MW). In Jammu and Kashmir, Uri (480MW) and Baglihar Stage-1 (450MW) are located in underground caverns.

North eastern states and Sikkim also come under Himalayan region and have huge potential for development of hydro power. Estimated hydro potential in north eastern states and Sikkim is 62,604MW with many large hydropower projects identified in Brahmaputra and Teesta river basins. Currently, only 1,242MW of electricity is being generated in north eastern states and 16 hydropower projects totalling 5,576MW are under construction. In Sikkim, Teesta-V (510MW) power plant is in operation and other two, Teesta-III (1200MW) and Teesta-VI (500MW) are under construction and all of them are located in underground caverns.

Hydropower development in Bhutan

Bhutan currently produces 1,606MW of hydropower, which is about 6% of the estimated 24,000MW hydropower potential. By 2018, it is expected to reach 3,446MW. In the absence of oil and very minimum coal reserves, major thrust is on hydropower

and hydropower export (75% of total production) to India provide more than 40% of its revenue and constitutes 25% of its GDP. Major hydropower projects with large underground caverns, Tala hydroelectric project (1,020MW), Chukha (336MW) and Dagachhu (126MW) are in operation. Other major hydroelectric projects with large underground caverns, under construction are Punatsangchhu-I hydroelectric project (1,200MW), Punatsangchhu-II hydroelectric project (1,020MW) and Mangdechhu hydroelectric project (720MW) (Anon, 2015a, Anon, 2015b).

Hydropower development in Nepal

Nepal has an estimated potential of 83,000MW, of which 40,000MW is considered to be economical and technically viable. However, development of hydropower in Nepal has been sluggish and so far been able to develop only 680MW. Major hydroelectric projects in Nepal are Kali Gandaki (144MW), Middle Marsyangdi (70MW), Marshyangdi (69MW) and Kulekhani-I (60MW). However, many large hydroelectric projects are in planning stage and expected to come up in the near future (Sharma and Awal, 2013, Anon, 2016c).

1.2 GEOLOGICAL CHALLENGES IN TUNNELING IN HIMALAYAS

The Himalaya is the youngest mountain chain on the planet and is believed to be still evolving and has not yet stabilised geologically and geomorphologically. Indian Himalaya covers a stretch of over 2,500km and breadth of 250-300km from Jammu and Kashmir in the west to Arunachal Pradesh in the east. An area of about 5,33,604km² lies between 21° 57' - 37° 5' N latitudes and 72° 40' - 97° 25' E longitudes (Nandy et al., 2006). Fig. 1.4 shows Himalayan region in India. Physically Himalayas are divided into three parts separated by major geological fault lines as follows:

- Greater Himalaya (Himadri)
- Lesser Himalaya (Himanchal)
- Sub Himalayan Foothills (Siwaliks)

Himalayan region as a whole is affected by a constant tectonic uplifting as well as down cutting effects by several river systems. Himalayan topography typically consists of high hills and deep valleys with high gradients. Highly complex geological conditions exist due to active tectonics and structural discontinuities. Rock mass is subjected to varying in-situ stresses.

Fig. 1.4 Map showing the Himalayan region (Anon, 2008)

In addition, the compressional tectonic stress regime in the Himalaya has resulted in intense deformation of the rock mass, making it highly folded, faulted, sheared, fractured and deeply weathered. This complex geological setting has caused considerable stability problems and is a great challenge for successful tunnelling. Sharma and Tiwari (2012) discussed geological problems associated with tunnelling in Himalayas and were of the opinion that in tectonically active young mountains like the Himalayas, the rocks found during tunnelling are relatively incompetent and affected by a number of folds, faults and thrusts of various magnitudes and at many places are heavily charged with underground water. The most commonly encountered geological problems during tunnelling for hydroelectric projects in the Himalayan region are fault/thrust/shear zones, running ground conditions, squeezing, heaving and swelling, rock bursting, ground water inflow, wedge/block failures, hot temperature conditions, and gases in rock etc. Panthi (2007) summarised the factors adding to geological complexity in Himalayas as follows:

- Weak rock mass quality
- High degree of weathering and fracturing
- Rock stresses
- Ground water effect

Bedding and foliation that exist in the sedimentary and metamorphic rocks of Himalaya have made them highly directional affecting strength (strength anisotropy) and deformability of rock mass. This directional behaviour reduces the self-supporting capacity of the rock mass. Another major feature of the highly deformed rock mass of the Himalaya is frequent intercalation between different rocks and shear bands. On many occasions, thin bands of very weak and highly deformed rocks such as slate, phyllite, schists and sheared mylonites are intercalated within the bands of relatively strong and brittle rocks such as gneiss, quartzite and dolomite. These small bands of weak rock mass are squeezed and highly sheared within the stronger layers of rock mass. Being weaker in their mechanical characteristics and highly schistose, these shear bands lack sufficient bonding/friction and reduce self-supporting capability.

High degree of fracturing and weathering results in immediate tunnel collapse due to very low cohesion and friction. Fracturing in the rock mass results in many open channels facilitating the water inflow into the tunnels.

The third major stability problem faced during tunneling in the Himalaya is stress anisotropy. Due to topographic reasons, most of the tunnel projects are constructed in the Siwaliks and lesser Himalayan zones, where highly deformed rocks such as shale, mudstone, siltstone, slate, phyllite, schist, schistose gneiss and highly sheared fault gouge and mylonites are present. In general, highly deformed rock mass has very weak rock mass strength, and tunnelling through such rock mass may cause severe squeezing as soon as the overburden stress exceeds the rock mass strength. Severe squeezing has been observed even with relatively low overburden, where tunnels pass through highly sheared fault zones with extremely poor rock mass (Panthi and Nilsen, 2007).

The fault zones, sheared zones, fractured and weathered rock mass of the Himalaya are highly permeable and water bearing. Tunnelling through such permeable zones always poses great difficulties and considerable challenges. The severity of the problems caused by water inflow and leakage are huge in the Himalayas.

1.3 STATEMENT OF THE PROBLEM

In many cases, underground caverns are constructed in adverse geology, and in some cases, exist in close proximity to major geological structures like Main Central Thrust (MCT) and Main Boundary Thrust (MBT) etc. Construction of major underground caverns under such conditions poses difficulties, with respect to stability, as proper choice of support becomes a complex issue. Generally, the choice of supports under such conditions is mainly done using the rock mass classification systems such as “Q”, “RMR” or “GSI”. There are many disadvantages of using these systems and in many cases, it gives a qualitative description of the support system. Improper choice of the support system may lead to the failure of support and in turn may lead to failure of the structure. There are many cases where in, the designed supports have failed to provide adequate resistance causing grave consequences by jeopardising the stability of the caverns.

Every underground excavation project in Himalaya starts with lot of uncertainties as adequate pre-construction stage investigations are not carried out as they are difficult to carry out or quite expensive and time taking. Some of the ground control issues faced while constructing large caverns are as follows:

- Structurally controlled failures at shallow depths, if in-situ stresses are not adequate and supports are not put on time, any opening up of joints can trigger roof fall or wedge failures, particularly in the roof of cavern.
- Sudden geological surprises like shear zone, fractured zone. If preparedness to deal with such situations is not there, it can hamper the progress. Also, if not dealt with proper treatment, may influence the stability of the cavern, with further excavation.
- Sudden in-rush of water can create serious strata control problems. If correct assessment of its source and method to deal with are not done, it can halt the progress of the cavern/tunnels for years. There was one such case in Himalaya where sudden in-rush of water halted the tunnel boring machine (TBM) for many years.
- High wall displacements or convergence of walls far more than the design limits may affect installation and maintenance of utilities.

- Failure of rock bolts and shooting out of rock bolts in high stress regime were observed in many caverns in Himalayas and could be major strata control problem.
- Floor heave is likely and was reported from many caverns. If sufficient time is not allowed after complete excavation or if floor is not reinforced, it can hamper the progress and affect turbine foundation and alignment.
- Time dependent deformations can affect the working powerhouses.

Proper design and construction of the cavern is only possible, if the response of the surrounding rock mass is correctly understood during various stages of cavern excavation. A research study was taken up to assess stability of large caverns at various phases of excavation with a view to understand the rock mass behaviour. Study was continued during post excavation period to observe rock mass response after complete excavation.

In this study, an underground cavern site in lower Himalayas was selected at Tala Hydroelectric Project, Bhutan. At this site, two large caverns were excavated and behaviour of surrounding rock mass and the installed support during construction of the caverns was studied by monitoring the displacement of crown, side walls of the cavern and the load developed in rock bolts. The following stability issues were observed during the construction of caverns:

- Failure of the crown of powerhouse cavern.
- Large number of rock bolt failures in the side walls.
- Large displacement/convergence of side walls during construction and post construction.
- Recording of large load on steel ribs and appearance of tension cracks in cross tunnels.

In the caverns so far constructed in Himalayas, limited monitoring was done using geotechnical instruments during construction and there was no continuity of monitoring of same instruments during post excavation period. In this research study, an attempt is made to understand rock mass response at every stage of excavation by capturing them through instruments and simulate the same response in 3D numerical models. Study was carried out in following phases:

- Field investigations that included collection of rock samples for laboratory testing, rock mass characterisation and installation and monitoring of instruments at various stages of construction.
- Numerical modelling that included creation of 3D continuum and discontinuum models and calibration of the model with field measurements, assessment of stability of the cavern through model results.

A calibrated model could give insight into areas not covered by instruments and influence of other parameters on cavern stability, which are not measured in the field. Behaviour of the cavern was simulated using both continuum and discontinuum 3D numerical models.

Stability of the cavern was assessed based on combined approach utilising, calculation of strength to stress ratio, strain on the walls, field measurements and physical observations. Cavern orientation with principal stress direction is an important parameter that governs the stability of cavern. Parametric study was done using the calibrated model for different orientation of the cavern. Stress distributions in the pillar and side abutments were studied. Sensitivity analysis was carried out to identify the most sensitive parameter among the parameters used in 3D numerical modelling.

1.4 ORGANISATION OF THE THESIS

This thesis is divided into chapters for disseminating relevant information. Chapter -1, briefly introduces the research topic giving the background information. Available literature and latest developments in this area of research are briefly outlined in Chapter-2. Investigations carried out during this research study (both field investigations and numerical modelling studies) are explained in Chapter-3. Results of instrumentation from field investigation and 3D numerical modelling results are analysed and presented in Chapter-4. Conclusions drawn from the research study and suggestions for future research are presented in Chapter-5. Research findings from other researchers and other relevant references are listed out in Reference section. Details of field data and other supplementary information are appended at the end of the thesis.

LITERATURE REVIEW

Stability of large underground caverns revolves around interaction of surrounding rock mass with the cavern and its support elements. There are two factors, fixed one like geological setup, in-situ state of stress and variable factors like shape and size of cavern, orientation of cavern, existence of other caverns in the vicinity, method of excavation and finally support elements provided to aid its interaction with the surrounding rock mass, that determine the stability of the cavern. Interaction of cavern in Himalayas is more complex due to variable geological setup and in-situ stress regime. Many researchers have contributed to understanding the mechanics involved and in-turn facilitated in improving the stability so that the very purpose of the cavern is justified both technically and economically. Some of the important research leading us to present status of understanding of caverns is presented below.

2.1 CAVERNS

An underground opening having a cross sectional area of 120m² or more and an axial dimension of not exceeding 15 times the lateral dimension is classified as a “Cavern” (Sinha, 1989). Caverns are constructed to cater facilities such as underground powerhouses, pumped storage units, storage of food, drinking water, oil and other liquid hydrocarbons, pressurised gas and air, industrial waste, subway stations, sewage treatment plants, parking garages, swimming pools, shelters, testing facilities, military facilities and for recreational uses. Broch (2016) reviewed extensive use of rock caverns in Norway.

Traditionally, roof of the cavern is a circular arch, but could be changed to multi-radial or elliptical to suit the host geology. Trapezoidal roof with side haunches limiting the length of flat spans of the roof were used for the caverns at Drakensburg (South Africa), and Poatina (Tasmania, Australia). The sides of cavern could remain straight or curved. The invert of the cavern could be straight or remain curved. In South Korea, mushroom and egg shaped caverns have been constructed. Numerical analysis by Lee et al. (2003) showed that egg shaped cross section provides many advantages in structural stability. Some of the shapes of the cavern generally used are shown in Fig. 2.1.

Fig. 2.1 Different geometrical shapes of caverns (Saurer et al., 2013)

2.1.1 Choice of Cavern Shapes

Conventional shape chosen for an underground powerhouse cavern in competent rock mass is circular arch. Arched roof provides stability in the rock mass above the cavern roof with uniform stress distribution and also provides convenient headroom for an overhead crane and ventilation ducts. Also, sidewalls are simple to excavate by vertical drill-and-blast benching and provide straight walls for crane column location and utilization of space to the maximum extent possible. However, problem with this cavern shape when used in weak rock masses, particularly with high horizontal in-situ stresses, is that tall straight sidewalls tend to deflect inwards and tensile failure is induced as shown in Fig. 2.2 (Hoek, 2000). Stabilisation of the rock mass surrounding this cavern requires significant reinforcement in the form of grouted cables or rock bolts. Under such condition, use of elliptical shape is a practical choice, which can reduce the failure zones substantially and the support requirement.

Elliptical shape has been used in Waldeck II cavern in Germany and Singkarak cavern in Indonesia (Lottes, 1972). Although, elliptical shape is better from geotechnical point of view, it has some practical disadvantages. Cavern shape is such that the construction has to be more carefully executed than the conventional straight-walled cavern and items such as the cranes and services have to be designed to fit into the cavern shape. These differences can create significant problems where the skill of workforce is limited.

Each scheme should be investigated on its own merits, taking into account construction problems as well as geotechnical factors. In some cases, the use of an elliptical cavern

shape may be justified but, in general, the conventional cavern shapes with circular arch or mushroom shaped arch may be suitable except for very weak rock masses.

Fig. 2.2 Conventional arched roof cavern vs elliptical cavern (Hoek, 2000)

2.1.2 Cavern Orientation and Location

Optimum orientation for a cavern is the direction which utilizes the rock arching action to the maximum extent. This is normally achieved by aligning the cavern in a direction normal to the strike direction. However, orientation of geological discontinuities such as joints, slip planes and seams and identification of favorable and unfavorable joint sets is equally important while deciding the orientation of cavern. Indian standard, IS 9120-1979 states that a machine hall cavity may be aligned on the basis of an optimum compromise between the direction of the ruling strike and the direction of such features so as to ensure that inferior rock formation is confined to the shortest dimension of the cavity.

There are many constraints in selecting the cavern location. Some of the main constraints are location of portals, access tunnels, size and operation of the cavern facility, utilization of maximum water head in case of hydro projects (Anon,1992). Within such constraints the cavern location should be optimized with respect to the topography and geology. Some important factors in this optimization are:

- a. Adequacy of rock cover.
- b. Avoidance of weakness zones or the crossing of them in the shortest possible duration.
- c. Avoidance of adverse orientation relative to major joint sets.

- d. Sufficient depth below the groundwater table.
- e. Avoidance of rock with abnormally low stresses, giving reduced confinement.
- f. Avoidance of rock with very high stresses.

Minimum rock cover

Minimum rock cover is the most important parameter for shallow caverns. Minimum rock cover should be able to give adequate normal stresses on joints such that joints don't open up and aid natural arch and self-supporting as far as possible. Minimum rock cover required can be a major constraint on cavern location and is determined from an assessment of many factors, which may include:

- Quality of the geological information.
- Rock properties.
- Thickness of superficial deposits.
- Depth of weathering.
- Cavern span.
- Cost implications.

As a general rule, the minimum cover of strong rock should be at least equal to half the cavern span. However, many large span tunnels and caverns have been constructed with rock cover of one fourth of the cavern or tunnel span. In the Valerenga road tunnel in Oslo, Norway, rock cover down to 3.5m was adopted for a span of 12.6m (Anon, 1992). A minimum rock cover in weak rock above the crown of large caverns should be preferably three times the width of cavern.

In general, reduced rock cover increases the cost of geotechnical investigations and rock support requirement and this cost is offset by advantages in adopting reduced cover. Reduced rock cover is normally limited to small areas, such as the section of cavern closest to the portal. Design of such low cover is only acceptable where the fresh rock surface is competent and fully understood with detailed site investigations.

Jointing

Stability of the cavern and the amount of overbreak is influenced by orientation of joints with respect to the axis of the excavation. Properties of the in-situ rock mass are largely governed by the properties of joints and discontinuities. This is the case, even for strong and hard rocks. Joints transfer compressive and shear forces, but not tensile forces. Two main methods of rock mass classification, Q-system (Barton, 1974) and RMR (Bieniawski, 1989) take into account the influence of joint orientation on rock classification and support requirements. If the angle between the excavation axis and the strike of a major joint set is small, say less than 30° , the amount of overbreak is likely to increase. Joint characteristics can have major influence on the orientation of caverns. For caverns with long and high walls, it is important to have an angle of at least 25° to the strike of steeply dipping discontinuities.

It is necessary to carry out a detailed survey of the bedding or foliation and the jointing of the rock mass so that optimization of the direction of the excavation axis with respect to joint orientation could be done. For openings situated at shallow or intermediate depths, the longitudinal axis of the cavern is ideally oriented along the bisection line of the largest intersection angle of the strike of the two dominant sets of discontinuities (joints, bedding or foliation). Close alignment with any further joint sets may be avoided, so as to reduce the extent of potentially unstable rock (Jack and Parry, 2015).

Weakness zones

Weakness zones are defined as zones that are weaker than the surrounding rock mass. Thickness of a weakness zone can range from a few centimeters to several hundred meters. Weakness zones may be in the form of weak rocks, faults, shear zones, heavily fissured zones, hydrothermally altered rocks and deeply weathered zones. Cost of cavern construction can be strongly influenced by the presence and nature of the weakness zones encountered and the mode of treatment. Many major problems in underground construction are related to such zones and the cost implications can be considerable. These problems commonly result in poor stability of unsupported rock and heavy inflows of water from fissured zones. It is, therefore, important that weakness zones are identified and, if possible,

avoided. If the space between faults, gouges, crushed zones or weathered seams is too small for the cavern space, the different zones have to be evaluated and a location is chosen that gives the minimum excavation in these difficult materials. Alternatively, a different cavern geometry that fits between the weakness zones may be considered. Consideration should be given to the orientation of the weakness zones in the rock mass, as steeply dipping features can have a major influence on the stability of walls, while flat lying ones can be a threat to roof stability. Although, it may not be possible to completely avoid weakness zones, their influence on the cavern stability can be minimized by identifying them in advance and with proper treatment.

In-situ stress condition

In-situ stresses in rock mass can have one or more origins. Gravitationally induced stresses and tectonic stresses are often the major components, but residual stresses, the locked in stresses resulting from the stress history of the rock, can be significant. Rock stresses are also influenced by structural heterogeneities, such as major weakness zones, where highly anisotropic stress conditions can occur. Grov and Lu (2015) discussed importance of in-situ stresses in design and building of rock caverns and requirement of sufficient in-situ horizontal stress for maintaining large span.

In-situ stresses and redistribution of stresses with cavern excavation greatly influence the stability of cavern. Orientation of cavern axis with the direction of principal stress can greatly influence the behavior of cavern. Generally, it is considered to have cavern axis parallel to major principal stress direction in order to minimize the ground control problems. It is also important to have required confining stress to achieve higher rock mass strength. In specific cases, increased stresses in the rock mass give rise to greater frictional forces on joints and thus greater rock mass strength.

Stresses in hard rocks are normally anisotropic. Degree of anisotropy can influence cavern stability and therefore optimal shape is very important in this case. Anisotropic and high stresses and accompanying stability problems can be associated with caverns constructed in high valley sides. Investigations for caverns in such locations must, therefore, establish if these conditions exist and appropriate designs are adopted. High tectonic and residual

stresses could have an influence on the location and shape of shallow caverns. According to Edvardsson and Broch (2002), in areas with high anisotropic stresses, the longer axis of the caverns should be oriented at an angle of 15° - 25° to the horizontal projection of the major principal stress to obtain the most stable situation regarding stress-induced instability.

Groundwater

Location of the water table and possibility of water flow through the joint network is an important factor while deciding the elevation of underground cavern. Some schemes require a constant seepage towards the caverns and for some uses, such as oil products storage and gas storage, the groundwater pressure is used to confine the oil or gas and is thus a prerequisite for successful implementation. For such cases, the groundwater pressure has to be maintained with water curtains. For other applications, the location of the groundwater is less important, and some caverns should ideally be placed above the groundwater surface to obtain as dry a cavern as possible. When the caverns are located in close proximity to shear zones or faults, water inflow may considerably alter the stability of caverns.

2.1.3 Cavern Layout

Design of cavern geometry and layout of a system of caverns is generally based on objective of the cavern, various essential components in the system, their orientation and dimensions and importantly, cost of excavation and support and cost of maintenance during the service life. Ultimate aim is to create cavern space with least cost with maximum utilization of space and without compromising the safety. Main parameters defining cavern layout and geometry are the cavern size and shape and the spacing between caverns. In case of landslide prone areas, powerhouse should be deeper in the hill for protection from landslides. In case of large span, low gripping tension allows potential wedges to slide and destabilizes the excavation. Increasing span allows larger blocks to be relieved. Stability problems in caverns in general increase with increasing span. It is often preferable to meet the need for increased volumes by extending the opening along its length axis rather than increasing the span (Nilsen and Thidemann, 1993). The cavern should be placed deep

enough to give the normal stresses on joints and fissures, which are necessary for a self-supporting roof. It is also important to leave a reasonable layer of unweathered rock above the cavern. For more deep-seated caverns, it is important that the stresses don't exceed a level which can cause overstressed rock and stress-induced stability problems. Weakness zones and heavy jointing should also be avoided. Mapping and evaluation of jointing and weakness zones are important pre-construction phase investigations (Edvardsson and Broch, 2002).

In general, layout of the main caverns is given preference over the layout of other tunnels like, bus ducts, draft tubes, penstocks, tail race tunnels and other cross tunnels. Caverns and their spacing are favorably designed with respect to in-situ stresses and geological features compared to other associated tunnels as the size of other tunnels in the layout are small compared to the main caverns and can be managed even if they are oriented adversely. It is important to strike a balance between various issues involved in interaction of interconnecting tunnels with main caverns so as to produce economically viable and stable cavern layout.

2.1.4 Spacing between Caverns

Spacing between two caverns results in the formation of pillar, whose dimension is determined by other cross tunnels connecting the cavern. Width of pillars depends mainly on the rock quality, orientation of the discontinuities, cavern spans and heights and any openings formed in the pillars. In-situ stresses can also affect pillar widths, especially for caverns at depth. Pillar widths are normally equal to between half and the full cavern span or height, whichever is the greater (Anon, 1992). At the preliminary planning stage pillar widths should be conservative. As planning progresses on the basis of improved geological data, narrower pillars may be considered. As per Hoek (2007), pillar width should be preferably equal to one-half of the sum of widths of both the caverns or maximum height of adjoining openings, whichever is higher, depending on the general quality of rock masses.

Pillar dimension is an important parameter when multiple caverns are planned in close proximity. Estimates of acceptable pillar width can be made on the basis of assuming

kinematically possible sliding in unfavorable joints and calculating the factors of safety. Other approach is to calculate the pillar strength and pillar stress using various empirical formulae and calculate the factor of safety. Estimates of vertical stresses and joint shear strengths in the pillar are required for this type of analysis.

Zhao and Ma (2009) studied the influence of cavern spacing on the stability of adjacent caverns. Study was done for three different strengths of surrounding rock mass (soft rock ($E=18\text{GPa}$), medium hard rock ($E=40\text{GPa}$) and hard rock ($E=88\text{GPa}$)). One model included two caverns and the other model included three caverns. Numerical analysis was done under gravity loading and gravity plus earthquake loading. Damaged plasticity model with a non-associated potential flow was adopted for the surrounding rocks to study the effect of earthquake loading. Their results indicated that in the case of soft rock, if the spacing is less than typical length of one cavern (taken as largest width of a cavern in the group), the static and dynamic responses of adjacent caverns are significantly affected by their spacing. The damage and the distribution of tensile stress surrounding the caverns are extensive. Once the spacing approaches or exceeds twice the cavern length, the damage and the distribution of tensile stress of caverns keep unchanged, and the effect of nearby caverns disappears. Regardless of the strength of the rocks that the caverns are located in, once the cavern spacing is less than one cavern length (minimum length out of all caverns), the stability of adjacent caverns is severely affected by the cavern spacing. The damage and tensile stress areas of adjacent caverns are quite significant. The stiffer the rocks are, the smaller is the critical cavern spacing. The corresponding critical cavern spacing for the adjacent caverns located in soft rock, medium hard rock and hard rock is twice, less than twice, and one time the cavern characteristic length, respectively. Once the cavern spacing exceeds the critical cavern spacing, the static and dynamic damage and the distributed area of tensile stress will hardly develop any further and the cavern spacing will have insignificant influence on the stability of adjacent caverns. In some situations, as the rock strength decreases, the damage becomes more severe and the area of tensile stress becomes more extensive. The critical distance of cavern spacing decreases as the strength of the surrounding rocks increases. Abolfazal and Hossein (2014) determined the rock pillar

between two adjacent caverns in Iran based on ratio of elasto-plastic and elastic displacement and the plastic zone determined by numerical modelling.

2.2 MAJOR UNDERGROUND CAVERNS IN INDIA

Brief information about major hydroelectric projects with underground caverns in India are given here. Some of major underground hydroelectric projects with underground caverns are:

1. Nathpa Jhakri hydroelectric project (1500MW)
2. Sardar Sarovar hydroelectric project (1200MW)
3. Teesta III hydroelectric project (1200MW)
4. Karcham Wangtoo hydroelectric project (1000MW)
5. Tehri hydroelectric project (1000MW)
6. Koyna IV hydroelectric project (1000MW)
7. Srisaillam hydroelectric project (LBPH 900MW)
8. Tapovan Vishnugad hydroelectric Project (520MW)

1. Nathpa Jhakri hydroelectric project (1500MW)

Nathpa Jhakri hydroelectric power project is the largest hydroelectric project in India with installed capacity of 1500MW (Fig. 2.3) It is a run of the river scheme project on river Sutlej situated in Kinnur district of Himachal Pradesh. The salient features are:

- 62.50m high concrete dam.
- Underground desilting complex, comprising four chambers, each 525m long, 16.31m wide and 27.5m deep, which is one of the largest underground complexes for the generation of hydro power in the world.
- 10.15m diameter and 27.394km long head race tunnel, which is one of the longest hydro power tunnels in the world, terminating in a 21.60m/10.20m diameter and 301m deep surge shaft.

- Underground power house with a cavern size of 222m x 20m x 49m having six Francis turbine units of 250MW each, to utilize a design discharge of 405cumecs and a design head of 428m.

Fig. 2.3 Powerhouse cavern of Nathpa Jhakri hydro electric project, Himachal Pradesh (Hoek, 2000)

2. Sardar Sarovar hydroelectric project (1200MW)

Sardar Sarovar project, on the right bank of river Narmada, has two powerhouses, the river bed powerhouse and canal head powerhouse with installed capacity of 1200MW and 250MW respectively. The river bed powerhouse is an underground powerhouse. Underground powerhouse complex consists of powerhouse of 23m wide, 57m high and 210m long. There are six pressure shafts of 9m diameter for intake of water from the reservoir to the powerhouse and six draft tubes of 16m wide double D shaped for drawing out water to collection pool. On the downstream side, there are three D-shaped bus galleries of 12m wide and 7.5m high connected to bus shafts. There are a few interconnecting tunnels and access tunnels, which are close to the powerhouse.

3. Teesta III hydroelectric project (1200MW)

Teesta Stage III is one of the largest hydropower plants in India under construction, with a head of 800m. It is located in the north eastern state of Sikkim. The project comprises of 60m high concrete face rock fill dam (CFRD), with the two bays of chute spillway on the left bank, two desilting chambers of size 320m (l) x 17m (w) x 23m (h) and about 13.8km long 7.5m diameter head race tunnel to carry water to the underground powerhouse (214.3m x 21.3m x 44.8m) to feed six units of vertical pelton turbines.

4. Karcham Wangtoo hydroelectric project (1000MW)

Karcham Wangtoo hydroelectric project is a run-of-the-river hydroelectric power station on the Sutlej river in Kinnaur district of Himachal Pradesh. Presently it is the largest hydroelectric project in the private sector in India. There is a concrete gravity dam of 43m high above the river bed. The dam is having six sluice spillway bays of size 9m (width) x 9m (height). Other main components are a 10.48m diameter, 17.2km long headrace tunnel; 4.75m diameter four pressure shafts; an underground powerhouse (187m x 21.6m x 52m) and transformer hall (116.5m x 15m x 24.2m) with 4 x 250MW installed capacity and 909m long and 10.48m diameter tailrace tunnel.

5. Tehri hydroelectric project (2400MW)

Tehri hydro power complex (2400MW), comprises of the following components:

- Tehri dam and hydro power plant (HPP) (1000MW)
- Koteshwar hydro electric project (400MW)
- Tehri pumped storage plant (PSP) (1000MW)

The 1000MW Tehri dam and hydro power plant is under operation and other two components are under construction. The 1000MW Tehri HPP comprises a 260.5m high Tehri dam, which is the highest earth and rockfill dam in the Asian region, two numbers of head race tunnels, an underground hydro powerhouse complex with machine hall (197m x 22m x 47.2m) and transformer hall (161m x 18.5m x 29m) having four conventional turbine/generator sets of 250MW each. Spillway system comprises chute spillway, two gated shaft spillways and two ungated shaft spillways.

6. Koyna IV hydroelectric project (1000MW)

Koyna dam is a rubble concrete dam constructed across river Koyna, a tributary of Krishna basin in Satara district, Maharashtra, The dam is founded on basalt rock. Koyna is one of the major hydroelectric projects in the country and impound (initially 2797.4Mcu.m) water to generate 1920MW power in four stages. Dam is 103.2m high above the deepest foundation and its total length is 807.22m. There are in all 53 monoliths of which six end monoliths are constructed in masonry and the rest in rubble concrete. Spillway is centrally located and extends from monolith no 18 to 24 over a length of 88.70m.

Koyna stage IV (100MW) has many underground components, as given below:

- Underground machine hall (145m x 20m x 50m)
- Transformer hall (173m x 20/18m)
- Head race tunnel (7m x 9.5m and 4.22km long)
- Tail race tunnel (10m x 10m D shaped 1.94km long)

7. Srisaillam hydroelectric project (LBPH 900MW and RBPH 770MW)

Srisaillam dam is constructed across the Krishna river at Srisaillam in Kurnool district of Andhra Pradesh and is the 2nd largest capacity hydroelectric project in the country. Dam was constructed in a deep gorge in the Nallamala hills, 300m above sea level. It is 512m long, 240.79m high and has 12 radial crest gates. It has a huge reservoir of 800sq.km. The left bank hydroelectric power station generates 6 x 150MW of power and right bank generates 7 × 110MW of power.

Underground hydropower complex of the Srisaillam left bank project consists of three large caverns, powerhouse (236.2m x 25.7m x 52.4m), transformer hall (176m x 16.2m x 26.5m) and surge chamber (181.6m x 18m/24m x 74.5m). There are six pressure shafts joining the powerhouse on the upstream side and six bus ducts joining the powerhouse and the transformer hall caverns. There are six draft tubes between powerhouse and the surge chambers.

8. Tapovan Vishnugad hydroelectric project (520MW)

Tapovan Vishnugad Hydroelectric Project (4 x 130MW) is a run-of-the-river scheme being executed by NTPC Ltd. in the state of Uttarakhand. It is a project on river Dhauliganga, a tributary of Alakananda. Powerhouse complex is located on the left bank of Alakananda near Joshimath. The scheme involves construction of 70m long barrage, 12km long head race tunnel (HRT) and powerhouse of 520MW installed capacity along with other appurtenant structures.

Underground powerhouse complex consists of underground excavations, powerhouse (158.5 x 22.3 x 48.6), transformer hall (147.75m x 18.3m x 27.8m) and bus ducts (2 nos. of 12m x 8m D shaped tunnels). Underground caverns of Tapovan Vishnugad project is shown in Fig. 2.4.

Fig. 2.4 Powerhouse and transformer hall caverns of Tapovan Vishnugad hydroelectric project, Uttarakhand (NTPC Ltd.)

Some of the large hydroelectric power plants, where underground caverns (powerhouse (PH), transformer hall (TH) and surge chamber (SC) exist are listed in Table 2.1.

Table 2.1 Major underground caverns in hydroelectric projects in India

Name of Project	State	Capacity (MW)	Size of Cavern [L (m) x W(m) x H(m)]	Status
Nathpa Jhakri	Himachal Pradesh	1500	PH 222 x 20 x 49 TH 196 x 17.5 x 27.4	Completed

2.3 ROCK ENGINEERING TOOLS FOR STABILITY EVALUATIONS OF CAVERNS

Response of surrounding rock mass when the cavern is excavated needs to be quantified to assess the stability of cavern. Assessment of stability condition of a cavern requires integration of geological, geotechnical, in-situ stress and hydrological parameters. Various rock engineering tools are available to assess the ground behavior with a view to optimize the cavern design parameters. Stille and Palmstrom (2003) presented principal relationships between ground behavior and rock engineering and design tools. Although, it is applicable in general to any underground excavation, it is relevant for cavern excavation and is presented in Fig. 2.5.

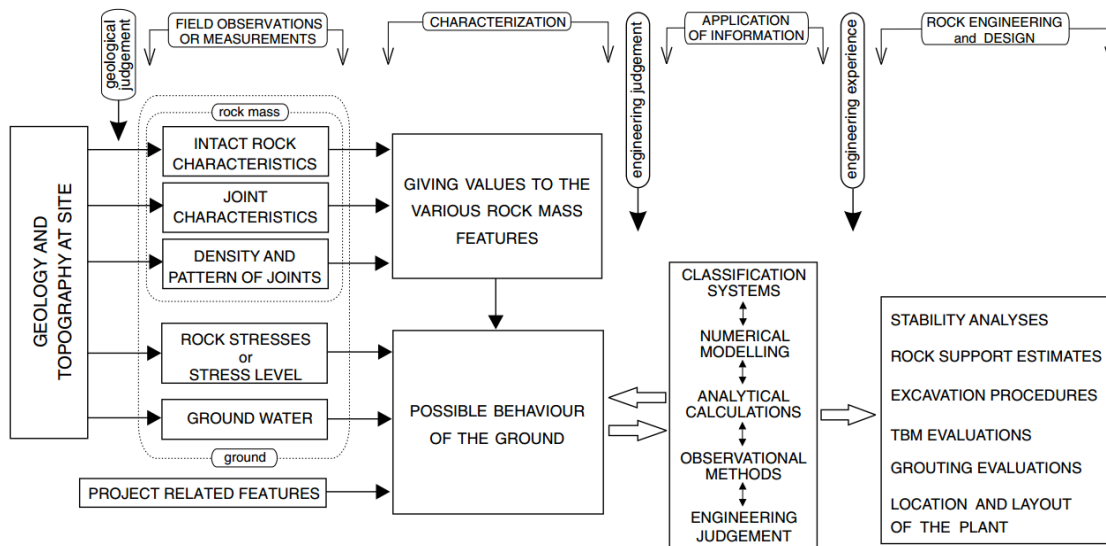

Fig. 2.5 Principle relationships between ground behaviour and rock engineering and design (Stille and Palmstrom, 2003)

As per Bieniawski (1984) “Provision of reliable input data for engineering design of structures in rock is one of the most difficult tasks facing engineering geologists and design engineers.”. Under such condition, frequently, the design of tunnels and caverns is based on observations, experience and personal judgement, where empirical design methods such as rock engineering classification systems play an important role. Palmstrom and Stille (2007) discussed the current rock engineering tools in the following headings:

- Empirical methods (rock engineering classification systems)

- Analytical and numerical methods

Palmstrom and Stille (2007) presented simplified diagram for selection of design methodology based on the behaviour (instability) of rock excavations as given in Fig. 2.6.

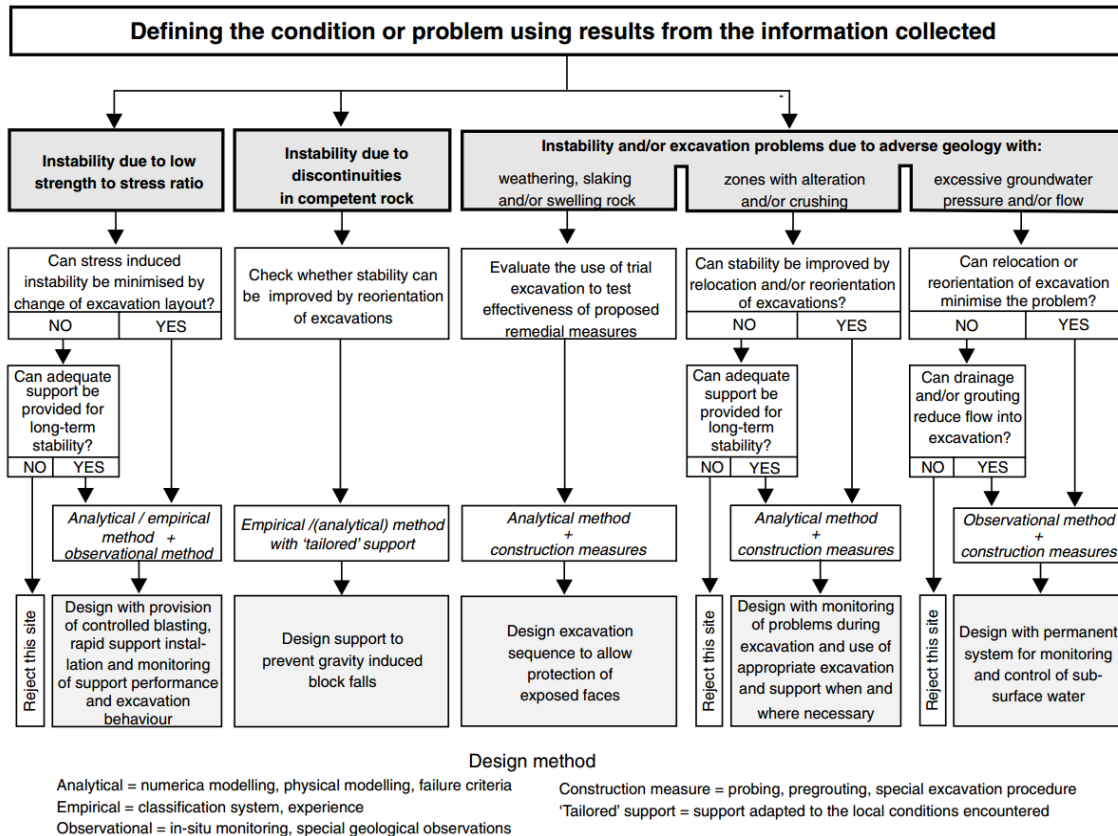

Fig. 2.6 Simplified diagram for selection of design methodology (Palmstrom and Stille, 2007)

2.3.1 Empirical Methods

Rock mass classification systems have been in use for more than 40 years. Some of the classification systems developed are aimed to characterize the rock mass or to give design inputs. Some of the popular systems are Rock Mass Rating (Bieniawski, 1976, 1989), Q (Barton et al. 1974, 2014), Geological Strength Index (Hoek, 1994), and Rock Mass Index, (Palmstrom, 1995).

Detailed description of these methods was given by Hoek, (1999), Hudson and Harrison (1997). Milne et al. (1998) lists the aim of rock mass classification systems as:

- To identify zones of material of similar geo-mechanical characteristics.
- To provide an indication of predicted stability for excavations of a given size.
- To aid in the selection of an appropriate support strategy.
- To provide an indication of in-situ rock mass strength, modulus of deformability, etc.

Use of rock mass classification system is wide spread and generally preliminary design of rock support is usually made on the basis of guidelines listed in popular rock mass classification systems such as Q-system or the RMR in the absence of any specific guidelines for caverns. These methods allow the suitable type of support to be determined for various rock classes that have been identified during cavern excavation. These methods may also be used for the final design, which necessarily involve their use during construction. Both methods may be used in parallel for complex and difficult ground conditions and the results compared. Rock bolt lengths are estimated on an empirical basis taking into account block size in the case of spot bolting, and cavern span in the case of systematic bolting. Only recent updates in popular methods like RMR, Q and GSI are discussed below.

Q-system for rock mass classification and support estimation

The Q-system was developed by Barton et al. (1974) at NGI (Norwegian Geotechnical Institute) after analyzing 212 tunnel case studies. In 1993, Q system was updated with analysis of additional 1050 additional tunnel case records (Grimstad and Barton, 1993). It was further modified in 2007 with 800 additional case histories (Grimstad, 2007). The method is empirical and is based on the Rock Quality Designation, RQD (Deere, 1963), and five additional parameters, number of joint sets, joint roughness and alteration (infilling), amount of water and various adverse features associated with loosening, high stress, squeezing and swelling. The Q-system also takes account of the intended use of the excavated space. Latest updated chart of Q with suggested support measure is shown in Fig. 2.7. The Q-value is expressed by the formula:

$$Q = \frac{RQD}{J_n} \times \frac{J_r}{J_a} \times \frac{J_w}{SRF} \quad (2.1)$$

where,

RQD = Rock Quality Designation

J_n = Number of joint sets

J_r = Joint roughness parameter

J_a = Joint alteration or filling parameter

J_w = Water pressure or leakage parameter

SRF = Stress reduction factor

REINFORCEMENT CATEGORIES

- 1) Unsupported
- 2) Spot bolting, sb
- 3) Systematic bolting, and unreinforced or fibre reinforced shotcrete, 5-6 cm), Sfr/B+S
- 4) Fibre reinforced shotcrete and bolting, 6-9 cm, Sfr+B
- 5) Fibre reinforced shotcrete and bolting, 9-12 cm, Sfr (E700) +B
- 6) Fibre reinforced shotcrete and bolting, 12-15 cm, Sfr (E700) +B
- 7) Fibre reinforced shotcrete > 15 cm + reinforced ribs of shotcrete and bolting, Sfr (E1000) +RRS+B
- 8) Cast concrete lining, CCA or Sfr (E1000) +RRS+B

The bolts are 20 or 25 mm in diameter

E) Energy absorption in fibre reinforced shotcrete at 25 mm bending during plate testing

$\left[\begin{array}{l} D45/6 \\ \text{c/c } 1.7 \end{array} \right]$ = RRS with totally 6 reinforcement bars in double layer in 45 cm thick ribs with centre to centre (c/c) spacing 1.7 m. Each box corresponds to Q-values on the left hand side of the box

*) Up to 10 cm in large spans

**) Or Sfr+RRS+B

Fig. 2.7 Updated Q chart (Barton and Grimstad, 2014)

The numerical value of Q ranges from 0.001 for exceptionally poor quality squeezing ground upto 1000 for exceptionally good quality rock, which is practically unjointed. The six parameters, each of which has an importance rating and can be estimated from site investigation results and verified during excavation. In combination they represent:

- a. Block size by the quotient RQD/J_n .
- b. Inter-block shear strength by the quotient J_r/J_a .
- c. Active stress by the quotient J_w/SRF .

The equivalent span or height in Fig. 2.7 is found by dividing the actual excavation dimension by a factor, the Excavation Support Ratio (ESR value), representing the safety requirement for the use of the space. Developers of Q system have been updating the ESR values keeping in view of the demand for greater safety of the tunnels. The updated ESR values for different applications are given in Table 2.2.

Table 2.2 Excavation Support Ratio (ESR) values for use in Q (Barton and Grimstad, 1994, 2014)

	Type of Excavation	ESR (1994)	ESR (2014)
A	Temporary mine openings, etc.	ca. 2-5	ca. 2 -5 (No Change)
B	Permanent mine openings, water tunnels for hydropower (exclude high pressure penstocks), pilot tunnels, drifts and headings for large openings, surge chambers	1.6 – 2.0	1.6 – 2.0 (No Change)
C	Storage caverns, water treatment plants, minor road and railway tunnels, access tunnels	1.2 – 1.3	0.9 to 1.1 Storage Caverns 1.2 – 1.3
D	Power stations, major road and railway tunnels, civil defence chambers, portals, intersections	0.9 – 1.1	Major road and railway tunnels 0.5 to 0.8
E	Underground nuclear power stations, railway stations, sports and public facilities, factories, major gas pipeline tunnels	0.5 – 0.8	0.5 – 0.8

For underground power stations (caverns) ESR generally used is 1.0. The support derived from chart depicted in Fig. 2.7 is the permanent roof support. Evaluation of permanent wall support by this method requires a modification of the Q-value as shown below:

Q-value for roof (Q_r)

> 10

0.1 < to < 10

< 0.1

Q-value for wall (Q_{wall})5.0 x Q_r,2.5 x Q_r,1.0 x Q_r.

In order to calculate the Q-value for tunnel or cavern intersections, a joint set number value of **3 x J**, is normally used.

The use of the Q-system requires detailed engineering geological mapping and analysis of all the geological features encountered. The rock support evaluated from the Q-value and the corresponding tables give only probable amounts and support types to be used. During construction of the underground opening, the rock support types and quantities should be adopted to the observed rock conditions. The heterogeneous nature of rock masses precludes the design of definitive, cost-effective support systems prior to excavation. To simplify the classification of the rock mass quality and the rock support evaluation, it is common practice to divide the Q-value range into classes as indicated in Fig. 2.7.

Barton et al. (1994) found simple relationship between Q and observed deformation data from various tunnels. They found good agreement with measurement at Nathpa Jhakri powerhouse and Gjøvik Olympic cavern in Norway as illustrated in Table 2.3.

Table 2.3 Relationship between Q and deformation (Δ) (Barton et al., 1994)

$\Delta = \frac{\text{SPAN}}{Q}$	$\Delta_v = \frac{\text{SPAN}}{100Q} \sqrt{\frac{\sigma_v}{\sigma_c}}$	$\Delta_h = \frac{\text{HEIGHT}}{100Q} \sqrt{\frac{\sigma_h}{\sigma_c}}$	$k_o = \left(\frac{\text{SPAN}}{\text{HEIGHT}} \right)^2 \left(\frac{\Delta_h}{\Delta_v} \right)^2$
Nathpa Jakri power station cavern		Gjøvik Olympic cavern	
$\Delta_v = \frac{20,000}{100 \times 3} \times (6/35)^{1/2} = 28 \text{ mm}$ $\Delta_h = \frac{50,000}{100 \times 3} \times (4/35)^{1/2} = 56 \text{ mm}$ (SPAN = 20m, HEIGHT = 50m, Q = 3, $\sigma_v=4 \text{ MPa}$, $\sigma_h = 6 \text{ MPa}$, $\sigma_c = 35 \text{ MPa}$). (In the middle of the range of MPBX measurements for the arch and walls).		$\Delta_v = \frac{60,000}{100 \times 10} \times (1/75)^{1/2} = 6.9 \text{ mm}$ (SPAN = 60m, $Q_{\text{mean}} = 10$, $\sigma_v = 1 \text{ MPa}$ at 40 m depth, $\sigma_c = 75 \text{ MPa}$) (Almost identical to that measured with nine MPBX, and almost identical to UDEC-BB modelling results).	

Equations for estimating the deformation modulus for the rock mass (E_{mass}) relating it with Q and P wave velocity (V_p in km/s) suggested by Barton and Grimstad (2014) are given below:

$$E_{mass} = 10 \left\{ \frac{\sigma_c}{100} Q \right\}^{1/3} \quad (2.2)$$

$$E_{mass} = 10^{(V_P - 0.5)/3} \quad (2.3)$$

RMR classification

The RMR method of rock mass classification also called ‘Geomechanics Classification’ was developed by Bieniawski (1976) and he has revised the system over the years with inclusion of more case histories (Bieniawski, 1989). Following six parameters are used to classify a rock mass using the RMR system:

1. Uniaxial compressive strength of intact rock.
2. Rock quality designation, RQD.
3. Spacing of discontinuities including joints, faults, bedding planes, etc.
4. Condition of the discontinuities including aperture, continuity, roughness, wall condition and infilling.
5. Groundwater conditions where the effects of water on rock mass strength are taken into account.
6. Orientation of discontinuities.

In this system, the rock mass is divided into a number of structural regions and each region is classified separately. Boundaries of the structural regions usually coincide with a major structural feature such as a fault or with a change in rock type. In some cases, significant changes in discontinuity spacing or characteristics, within the same rock type, may necessitate the division of the rock mass into a number of small structural regions. Accordingly, rock mass is classified into five classes and support recommendations given by RMR system are given in Table 2.4.

Bieniawski (1976) showed that the relationship between RMR and the equivalent Q-values described by the equation:

$$\text{RMR} = 9 \log_e Q + 44 \quad (2.4)$$

Barton (1995) related RMR and Q as :

$$\text{RMR} = 15 \log Q + 50 \quad (2.5)$$

Table 2.4 Guidelines for excavation and support of 10 m span rock tunnels in accordance with the RMR system (Bieniawski 1989)

Rock Mass Class	Excavation	Rock Bolts (20mm diameter, Fully Grouted)	Shotcrete	Steel Sets
I – Very good rock RMR: 81 - 100	Full Face 3m advance	Generally no support required except spot bolting		
II – Good rock RMR: 61 – 80	Full Face 1 – 1.5m advance. Complete support 20m from face.	Locally, bolts in crown 3m long, spaced 2.5m with occasional wire mesh.	50mm in crown where required.	None.
III – Fair rock RMR: 41 – 60	Top Heading and Bench 1.5 – 3m advance in top heading Commence support in each blast. Complete support 10m from face.	Systematic bolts 4m long, spaced 1.5 – 2m in crown and walls with wire mesh in crown.	50-100mm in crown and 30mm in sides.	None.
IV – Poor rock RMR: 21 – 40	Top Heading and Bench 2.3 – 1.5m advance in top heading. Install support concurrently with excavation, 10m from face.	Systematic bolts 4-5m long, spaced 1.0 – 1.5m in crown and walls with wire mesh.	100-150mm in crown and 100mm in sides.	Light to medium ribs spaced 1.5m where required.
V - Very poor rock RMR: < 20	Multiple drifts 0.5 – 1.5m advance in top heading. Install support concurrently with excavation. Shotcrete as soon as possible after blasting.	Systematic bolts 5-6m long, spaced 1.0 – 1.5m in crown and walls with wire mesh. Bolt invert	150-200mm in crown and 150mm in sides, and 50mm on face	Medium to heavy ribs spaced 0.75m with steel lagging and forepoling if required. Close invert.

Geological Strength Index (GSI)

Since both RMR and Q classifications include RQD and in most of the weak rock masses, RQD is essentially zero or meaningless, an alternative classification system was developed by Hoek (1994). This system does not include RQD and places greater emphasis on basic geological observations of rock-mass characteristics, reflecting the material, its structure and its geological history and developed specifically for the estimation of rock mass properties rather than for tunnel reinforcement and support. GSI is closely associated with Hoek and Brown failure criteria. This system was initially developed for hard rock tunneling and later included poor quality rock masses and heterogeneous rock masses (Hoek, 1998, Marinos and Hoek, 2000, 2001). Charts for selecting GSI and its applications and limitations were well described by Marinos et al. (2000, 2007). GSI estimation from the given chart is purely qualitative and Hoek et al. (2013) proposed quantification of the GSI chart on the basis of two well established parameters, joint condition (Jcond89) rating defined by Bieniawski (1989) and the RQD defined by Deere (1963). Updated chart of GSI with these two parameter is shown in Fig. 2.8.

A fundamental assumption of the Hoek-Brown criterion for the estimation of the mechanical properties of rock masses is that the deformation and the peak strength are controlled by sliding and rotation of intact blocks of rock defined by intersecting discontinuity systems. It is assumed that there are several discontinuity sets and that they are sufficiently closely spaced, relative to the size of the structure under consideration, that the rock mass can be considered homogeneous and isotropic. These concepts are illustrated diagrammatically in Fig. 2.9.

Fig. 2.8 Quantification of GSI by joint condition and RQD (Hoek et al., 2013)

Fig. 2.9 Limitations on the use of GSI

2.3.2 Analytical and Numerical Methods

Analytical and numerical methods in cavern engineering can be divided into the following classes:

- a. Limit equilibrium methods for discrete blocks and wedges.
- b. Statistical-analytical methods, e.g. key block analysis.
- c. Numerical continuum methods, e.g. finite element methods and boundary element methods.
- d. Numerical discontinuum methods (distinct element methods).

For an analysis to be useful, it should address the factors that are important for cavern design. For example, the design of caverns planned at modest depths in hard rock is normally governed by the weakness zones and a series of intersecting joints, and not by in-situ or induced stresses and intact rock strength. Simple stability analysis of problematic areas using limit equilibrium methods are therefore, often used to supplement the support design given by the rock mass classification systems.

Sliding blocks and wedges

There are many published methods for determining the stability of blocks and wedges in excavated rock surfaces and the support required to achieve stability. These methods are based on limit equilibrium analysis. Hoek and Brown (1980) presented such methods. Similar analyses may be made to check pillar widths and their support requirements.

Key block analysis

Key block analysis may be used to determine which blocks in a cavern roof or walls control stability. Securing these key blocks will ensure overall stability. The analyses may be used to predict the likely location and appearance of key blocks using statistical joint data or joint maps taken from excavations when specific key blocks can be identified. The first mentioned use is an aid to recognizing the key blocks as such from the joint pattern observed. The ultimate purpose is to apply support where required and in the most cost-efficient way. The method is described in detail by Goodman and Shi (1985).

Numerical models

Numerical models are useful to evaluate qualitatively and quantitatively the effects of geology on the design. These methods can be used both in a forward analysis where, for given geometry and properties, results are obtained (for example stresses and displacements), or on a backward analysis where, given results or measurements, rock mass properties or rock mass behavior are approximated.

The interest of the design engineer is to assess the stability condition of the tunnel or cavern when no support is installed and when suitable support system is installed. Such assessment requires understanding the rock mass in terms of geological, geotechnical, in-situ stress and hydrological parameters. Further, the fundamental components of rock mass behavior needs to be accounted for using appropriate methods for the analysis of stresses and displacements in the rock mass around the tunnel and the associated structural components.

A number of methods of stress analysis are available from the closed form solutions to numerical models. Numerical modeling is a stress analysis technique, which uses the power of modern computers, numerical analysis technique and the principle of mechanics. With the rapid advancements in computer technology, numerical methods provide extremely powerful tools for analysis and design of engineering systems with complex factors that was not possible or very difficult with the use of the conventional methods, often based on closed form analytical solutions.

Rock mechanics problems of practical concern may not be solved analytically as the rock mass is inhomogeneous and the constitutive relations for the rock mass are non-linear and mathematical formulation of the problem is difficult. In such cases, approximate solutions may be found by computer-based numerical methods. In recent years, the development in the area of computational methods, numerical methods and rock mechanics has evolved many tools, which the rock mechanics engineer can use for the analysis.

Starfield and Cundall (1988) proposed a methodology for modelling rock mechanics problems and reference to this paper may be made for guidance and necessary cautions. Hoek et al. (1991) provided similar guidance with an overview on the use of various numerical modelling methods. Holling (1978) classified numerical modelling problems

into four regions according to the data available and the understanding of the problem as depicted in Fig. 2.10 (Holling, 1978; Hadjigeorgiou, 2012).

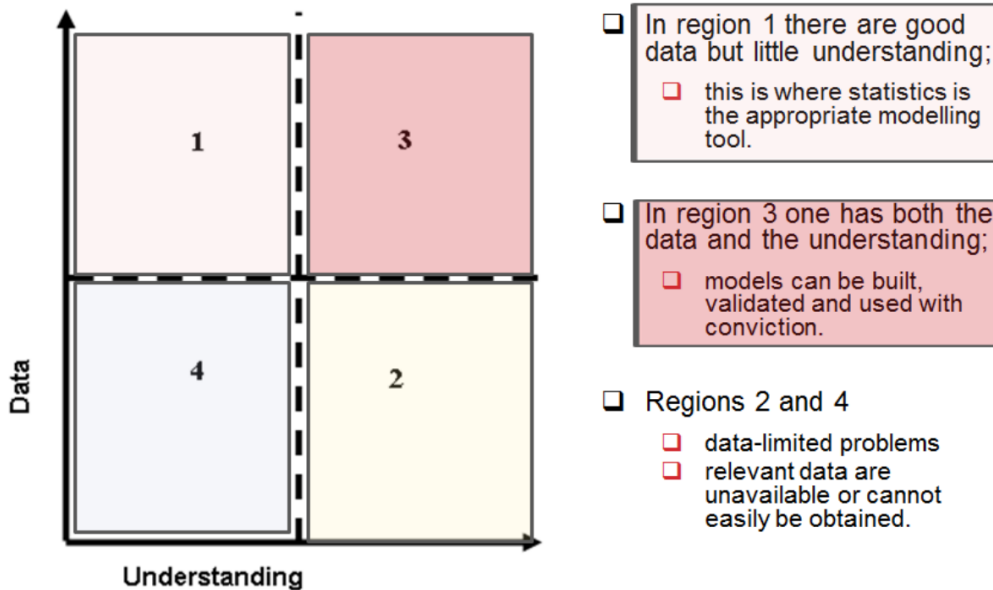

Fig. 2.10 Classification of modelling problems

In region 1, there is good data but poor understanding, and in region 3, there is both good understanding and good data. Regions 2 and 4 represent problems, where data is limited or cannot easily be obtained. Most problems in rock mechanics fall into this group of data-limited problems, whereas problems in structural engineering fall largely into region 3. Attempts have been made to collect sufficient data to move rock mechanics problems into region 3. This may, however, lead to more complex models and increasingly expensive ground investigations without significant improvements in understanding and design. Closed-form solutions that indicate the relations between stress and displacement around underground openings are available for simple excavation shapes in homogeneous ground conditions. These solutions have considerable value in providing a conceptual understanding of rock mass behavior and in testing numerical models.

Numerical models may be classed either as the continuum type or the discontinuum (Jing and Hudson, 2002; Jing, 2003). Continuum methods may include the discontinuities in the medium, if present, explicitly or implicitly, while in discontinuum methods discontinuities are incorporated explicitly. The need to use, for a particular problem, continuum or discontinuum methods depend on the size or scale of the discontinuities with respect to the size or scale of the problem that needs to be solved. There are no universal quantitative guidelines available to determine when one method should be used instead of the other one (Bobet et al., 2009). Brady (1987) provided some qualitative guidance in this respect is shown in Fig. 2.11.

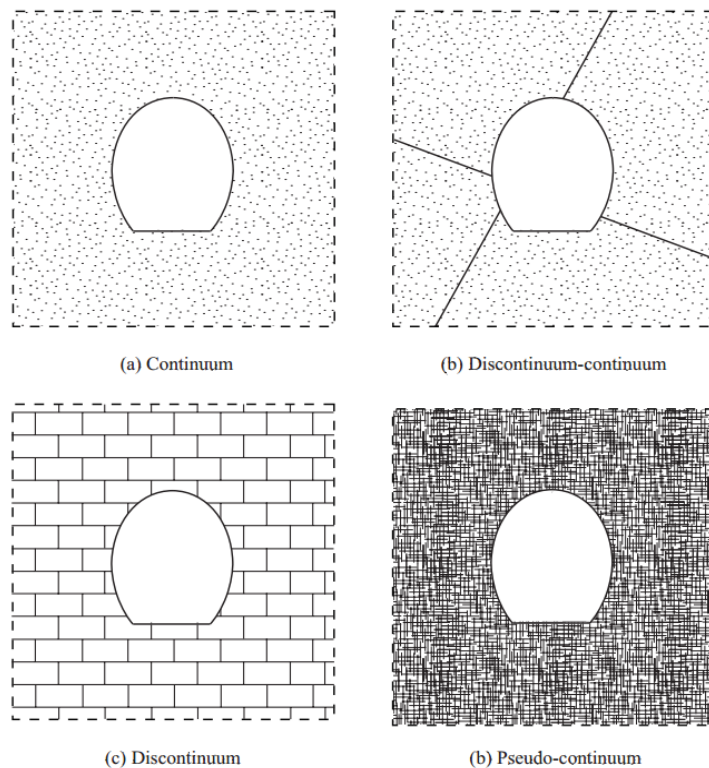

Fig. 2.11 Continuum and discontinuum models (Brady, 1987)

For example, Fig. 2.11a illustrates an opening in a medium without discontinuities. In this case, the displacement field is continuous and thus continuum numerical methods are appropriate. Fig. 2.11b shows a tunnel excavated in a medium with a small number of discontinuities that divide the medium into a small number of continuous regions. The displacement field will be continuous inside each region, but may be discontinuous across

the regions. If a continuum model is used, the model should be able to consider the specific discontinuities. The medium depicted in Fig. 2.11c is determined by a number of discontinuities with spacing and continuity such that the blocks defined are within the scale of the opening. In this case, displacements are determined by the slip along the discontinuities and rotation of the blocks. Thus a discontinuum numerical method is more appropriate. If the medium is heavily jointed such that the blocks defined by the discontinuities have a size much smaller than the opening, a pseudo-continuous displacement field is produced and the use of a continuum model (equivalent continuum) seems reasonable.

For continuum models based on the boundary element method, the free surfaces are divided into elements and the interior of the rock mass is treated as an infinite continuum. The stresses and strains applied to an element have a calculable effect on the other surface elements and throughout the medium. Thus changes at one surface element will affect all other elements. The method has the advantage that only the boundaries have to be divided into elements, and the far-field stresses are not influenced by the creation of an excavation. Although joints can be modelled by means of the displacement discontinuity approach, the boundary element method is not suitable for problems requiring explicit consideration of several joints or the sophisticated modelling of joint behavior. Also, in general, the method is not capable of incorporating variable material properties or modelling interaction between rock and support. Other numerical methods are more suitable for problems involving these considerations.

Continuum models based on finite element and finite difference methods relate the conditions at nodal points to the state within the elements. The physical problem is modelled numerically by discretizing the problem region. These methods have the advantage of being able to handle material heterogeneity and non-linearity, but they handle infinite boundaries poorly. Joints can be represented explicitly by means of specific joint elements, but generally in limited numbers.

The discrete element method considers blocky materials as a discontinuum and is well suited to modelling these highly non-linear problems. In this approach, the jointed rock

mass is represented by a series of blocks, each of which is considered a unique free body and can be discretized into deformable zones. The blocks can rotate, separate and slide according to Newton's second law of motion. The method has been until now primarily a research tool, but recently some understanding has been gained of where, how and when the method may best be applied.

Hybrid approaches to modelling can be used advantageously, whereby the desirable elements of each approach are retained and the undesirable aspects suppressed. Thus, the far-field behavior of material in a finite element analysis may be modelled by linking the outer elements to a boundary element system, which models the effect of infinite boundaries well. Following is a list of the numerical modelling codes most referenced in the literature:

- Finite Difference Method (FDM)
 - FLAC and FLAC3D (Itasca Consulting Group, Inc.)
- Finite Element Method (FEM)
 - ABAQUS (Hibbit, Karlson, and Sorensen, Inc.)
 - PENTAGON-2D and 3D (Emerald Soft)
 - PHASE2 (Rocscience)
 - PLAXIS (Plaxis BV)
- Boundary Element Method (BEM)
 - BEFE (coupled BEM-FEM), (Computer Software and Services) CSS
 - EXAMINE2D and EXAMINE3D (Rocscience)
- Distinct Element Method (DEM)
 - UDEC, 3DEC (Itasca Consulting Group, Inc.)
 - EDEM (DEM Solutions)
 - LDEC (licensed by Lawrence Livermore National Laboratory)
- Bonded Particle Method (BPM)
 - PFC2D and PFC3D (Itasca Consulting Group Inc.)

All codes are based on the principles of mechanics and they rigorously solve (in the context of numerical solutions) equilibrium equations, boundary conditions, strain compatibility, and the constitutive material model.

2.4 SUPPORT SYSTEM

In hard rock tunneling and cavern construction, the term 'bolt' normally refers both to tensioned bolts and fully grouted untensioned bolts, as the mode of action is dominantly in tension in both cases.

2.4.1 Spot Bolting

Design of spot bolting is done as excavation proceeds and is actually part of the construction process. Spot bolting is used to secure individual blocks of rock. The size of the block can be estimated from observation of the joints that define the block. The bolt should be long enough to obtain adequate anchorage in stable rock beyond the block. Block sizes are estimated from joint directions and spacing relative to the excavation.

Length of bolt should be 1 - 2m beyond the block, and preferably not less than 1.5m. Spot bolting at the excavation face is determined on the basis of experience as the time available precludes analysis. Some bolts are pre-tensioned to activate the anchorage and ensure that these are effective. It is good practice to assume that only half of the bolts will be effective, so the number of bolts is doubled, thus giving an added factor of safety over and above the factor of safety given by consideration of the ultimate load capacity of each bolt (Anon, 1992).

The number of bolts can be reduced with pre-tensioned bolts depending on the installation procedure and quality, as pre-tensioning gives assurance that they are carrying load. The extent to which joint shear strength can be taken into account varies with circumstances. For smaller blocks, joint shear strength is commonly ignored.

2.4.2 Systematic Bolting

Systematic bolting is used to achieve a general increase in stability. The bolts are normally installed in a pattern. The block size is the principal factor in determining bolt spacing and

cavern span dominates the determination of bolt length. Bolting is frequently done in conjunction with shotcrete or fibrecrete, and can be installed after its application.

Rock bolt spacing is conveniently estimated using Q-system or RMR classifications. Details of recommended support measures were adequately described by Barton et al. (1974), Bieniawski (1976, 1989) and Hoek and Brown (1980). Bolt spacing of 1 - 3m are indicated for most situations depending on the calculated rock quality. Bieniawski (1976) gave rock bolt spacing of 2.5m for RMR values of 61 to 80, 1.5m to 2m for RMR values of 41 to 60 and 1m to 1.5m spacing for RMR of < 41. No bolting is indicated for RMR value of > 80. Bolt spacing of less than 1m is not normally considered practicable and alternatives such as straps, shotcrete and fibrecrete may be considered in conjunction with bolting.

There are several means of estimating bolt lengths in common use. Schach et al. (1979) developed a formula giving bolt lengths in meters in accordance with common practice:

$$L = 1.40 + 0.184 B \quad (2.6)$$

where,

L = Bolt length, m

B = Cavern span, m

In any case the length should not be less than that required for spot bolting. Shorter bolts may be used towards the cavern walls, but should not be less than 2m. In some cases, it may be cost-effective to use two lengths of bolt alternately. Rock bolts placed systematically are in general located normal to the theoretical excavation line. Occasionally, a case may be made for angling the holes to take into account the joint directions, but the designer must take into account the added complication in installation and control.

Other empirical relationships defining the length and spacing of rock bolts are given in Tables 2.5 and 2.6 respectively.

Table 2.5 Empirical formulae, estimating length of rock bolts as a function of cavern span/height

Bolt Length (m)	Reference	Comment
$L= 0.3 \times S$	Farmer and Shelton (1980)	Span > 15m alternate with secondary bolting
$L=0.3 \times Sp$	Farmer and Shelton (1980)	Secondary bolting
$L= 0.67 \times S^{0.67}$	Lang and Bischoff (1984)	
$L= 2+ 0.15 \times S$	Hoek (2000)	Suited for weaker rock masses (roof)
$L= 2 +0.15 \times H$	Hoek (2000)	Suited for weaker rock masses (walls)
$L=1.40 + 0.184 \times S$	Myrvang (2001)	Norwegian Approach
L = Bolt length, S = Span, H = Height, Sp = Spacing of primary bolting		

Table 2.6 Empirical formulae for determining spacing between rock bolts

Spacing	Reference	Comment
$Spacing = \sqrt{T/P}$	Hoek (2000)	T= Working load of bolt or cable P= Support pressure
$Spacing = 0.5 \times L$	Farmer and Shelton (1980)	Primary Bolting
$Spacing = 0.5 \times L$ (Secondary)	Farmer and Shelton (1980)	Secondary bolting
$Spacing = 0.5 \times L$	Myrvang (2001)	Applicable to jointed rock mass
L = Bolt length		

2.4.3 Design of shotcrete and fibrecrete support

Both the Q-system and RMR method indicate the thickness of shotcrete support required for various rock qualities. With the development of the support method, fibrecrete technology has advanced significantly and has largely replaced mesh reinforced shotcrete. The support guidelines given by Barton et al. (1994) include a recommendation for very large thicknesses of shotcrete for some situations. This advice should be treated with caution as little advantage can be obtained by applying more than 200mm of shotcrete, when this is combined with rock bolting. This is particularly the case when the shotcrete contains steel fibre as reinforcement. However, thick layers of shotcrete may be applied occasionally to small areas of particularly poor rock.

As a general rule, systematic bolting with fibrecrete should be used for permanent support of roof of caverns that will be occupied most of the time or caverns that contain important processes or machinery. Shotcrete and fibrecrete support have a better effect if they act in unison with the rock bolts. The bolt heads should either be incorporated in the sprayed concrete or the bolts may be installed with bearing plates after spraying. In some situations the heads of the bolts may be protected prior to spraying concrete, and bearing plates and nuts installed afterwards. Plates installed after placing the shotcrete or fibrecrete support may require further sprayed concrete for corrosion protection.

2.4.4 Design of cast concrete support

Cast concrete support is not a realistic means of achieving general stability in cavern excavations, although it can be applied to limited areas of instability such as weakness zones. Stability of the rock mass is achieved primarily with rock bolts and sprayed concrete. A requirement for concrete lining is for reasons other than achieving primary rock stability and is subject to design on the basis of parameters other than those of rock mechanics. Operators may in some instances require an arched cast concrete roof as insurance against the fall of rock or loosened shotcrete.

2.5 STRESSES AROUND UNDERGROUND CAVERNS NEAR TOE OF SLOPES

Many hydroelectric projects, particularly in hilly terrains (like in Himalayas) are located at the toe of the hill or very close to the toe. In such cases, in-situ stresses vary abruptly depending upon the topography. Hoek and Moy (1993) discussed in detail about the distribution of in-situ stresses and factors that decide the location of underground caverns. Fig. 2.12a shows the maximum and minimum principal stresses in a gravitationally loaded slope with a far field horizontal to vertical in-situ stress ratio of 3:1. The in-situ stresses, particularly the minimum principal stress σ_3 , are significantly altered in the vicinity of the slope face as compared to the far field stresses. These local changes in the in-situ stress field influence the stresses induced in the rock mass surrounding an underground cavern located near the toe of slope.

Hoek and Moy (1993) also analyzed location of underground cavern at different distances from the toe of the slope using boundary element method. Contours showing zones in

which tensile and shear strength exceeded are shown in Fig. 2.12b. Failure trajectories in these overstressed zones indicate the direction in which failure of the rock would propagate, assuming the rock mass to be homogeneous.

**Fig. 2.12 a. Distribution of principal stresses in a gravitationally loaded slope
b. Zones of overstress and failure surrounding an underground cavern at different distances from the toe of the slope (Hoek and Moy, 1993)**

2.6 CRITICAL STRAIN OF ROCK MASS

According to Sakurai (1997), critical strain is a better measure of failure. The critical strain (mass) is defined as a ratio between UCS (qc_{mass}) and the modulus of deformation (Ed) of rock mass. He found that critical strain is nearly independent of joints, water content and temperature. Hence, equation for ϵ_{mass} is given as follows:

$$\epsilon_{mass} = \epsilon_r \left[\frac{E_r}{E_d} \right]^{0.3} \left[\frac{d}{S_{rock}} \right]^{0.2} \quad (2.7)$$

$$\geq \epsilon_\theta = u_a/a$$

where,

$\epsilon_r = q_c/E_r$ = Critical strain of rock material (obtained from tests in the laboratory)

ϵ_c = Tangential strain around opening

(observed deflection of crown in downward direction/radius of tunnel)

= u_a/a (Fig. 2.13)

S_{rock} = Average spacing of joints and

q_c = UCS of rock material for core of diameter, d .

Experience in Japan is that there were not many construction problems in tunnels where $\epsilon_\theta < \epsilon_{mass}$ or ϵ_r . It can be noted that critical strain appears to be somewhat size dependent according to equation 2.7. There is a lot of difference in predictions and actual observations in the tunnels. One has to give more attention to the joints. It is easier to observe strains than stresses in the rock mass. Sakurai (1997) classified the hazard warning level into three stages in relation to the degree of stability as shown in Fig. 2.13.

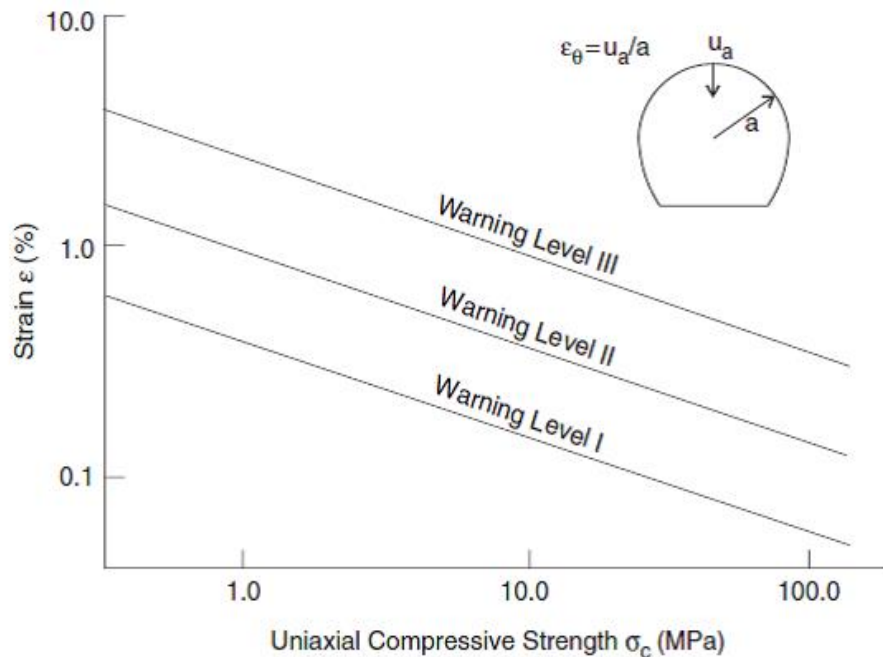

Fig. 2.13 Hazard warning levels for assessing the stability of tunnels (Sakurai, 1997)

He observed that where strains in the crown ($\epsilon_{\theta} = ua/a$) are less than the warning level I, there were no problems in the tunnels. Whereas, tunneling problems were encountered where strains approached warning level III. Swarup et al. (2000) have confirmed these observations in 19 tunnels in weak rocks in the Himalayas.

2.7 RESEARCH IN CAVERN STABILITY AND RELATED ISSUES

2.7.1 3D Physical Modelling Studies

In 1980's physical modelling was one of the main methods to identify the geotechnical problems. However, rapid developments in computational power and numerical methods, numerical modelling has become the preferred choice. Complexity and uncertainty of geological conditions and complex geotechnical issues have posed greater challenge to numerical modelling. Over a period of time, again significance of physical modelling has caught the attention of the researchers. Attempts are made to combine the advantages of both the models. Li et al. (2005) created a 3-D geo-mechanical model of the underground caverns of the Xiluodu hydropower station, China, combining the advantages some of the primary principles of the numerical method with the physical model process. Considering that the boundary condition has a great effect on the stress distribution, a larger test model was set up. The numerical discrete principle was also used to simulate an initial geo-stress field. As per the basic principle of cavern excavation that loading comes first, followed by excavation, a new technique, in which a high fidelity simulation of the excavation process and a very difficult cavern excavation were successfully achieved. The new method produced test results more satisfactorily, and this simulation was an obvious improvement of existing techniques. The results of the tests were compared with FLAC-3D model results. The displacement distribution form and global trend were the same in the data from both techniques, with a slight difference in the displacement values. The horizontal displacement results from the two methods were quite similar, but the vertical displacement in the numerical model was a little less than that of the physical model, which may be due to the fact that the numerical analysis did not simulate the joints and beddings as much as the physical model, and can not completely simulate the boundary conditions of the model.

Comparison of the two methods showed that the effect of the physical model test was satisfactory, and that some geological weak structures are difficult to simulate numerically. Both numerical simulations and physical model tests have their own advantages, and combining the advantages of the two methods enabled to overcome many difficult problems. For some moderate and small-scaled projects, numerical simulation can generally solve problems sufficiently. But for large or huge scaled underground projects, physical model testing is also a competitive method. To further the development of physical model tests, it is important to introduce more new and advanced technologies to be used in 3-D model tests.

Zhang et al. (2016) investigated the stability of an underground cavern group on the basis of large-scale 3D geomechanical model tests and numerical simulations. Multiple measurement techniques were developed to measure the convergence in the cavern, displacements at key points in the side walls and the damage pattern during the excavation process. The digital photogrammetric technique and fibre Bragg grating (FBG) based displacement sensing bars were applied to measure displacements in the surrounding rock mass. Mini multi-point extensometers with high-precision grating scales are developed as transducers for displacement monitoring. Results were compared with numerical modelling results of a nodal-based discontinuous deformation analysis method.

2.7.2 Borehole TV Camera

Yoshida et al. (2004) carried out borehole TV investigations to observe the behaviour of discontinuities during the construction of two large underground caverns in Japan. One was Okawachi power station with highly jointed rock mass and other one was Okutataragi power station with less jointed rock mass. Boreholes were drilled into the side walls of the cavern from a tunnel and behaviour of the discontinuities were measured before and after the excavation of the cavern.

Hibino and Motojima (1995) discussed the results obtained from in-situ measurements of rock behaviour at 16 caverns at underground power plants at Japan. These measurements were done using borehole camera, extensometers, convergence measurements etc. They

concluded that rock mass deformation mainly consists of ‘opening displacement’ (joint opening etc.) and ‘strain displacement’.

Maejima et al. (2003) characterised the behaviour of joints based on borehole camera investigation and finite element modelling based on micromechanics based continuum model (MBC Model). Borehole camera investigations showed that joint opening was taking place near to the walls of the cavern and displacements due to joint opening were more prominent than the displacement due to the strain in the rock. Joint data from these studies were incorporated in MBC model and good correlation was observed between results of MBC model and extensometer data.

2.7.3 Numerical Modelling Studies

The 62m span Olympic Ice Hockey Cavern was constructed in Gjøvik, Norway in 1991 with a cavern rock over of 25-50m only. Barton et al. (1994) predicted and measured the performance of the cavern using various tools like, rock stress measurements, cross hole seismic tomography, geotechnical core logging, Q-System of classification and modelled the cavern using UDEC-BB 2D numerical model. This model utilised the Barton-Bandis Joint model (Barton and Bandis, 1990) and predicted displacement of 4-8mm, which compared well with MPBX observation of 7-8mm.

Yoshida and Horri (1995, 2004) developed constitutive model of a rock mass containing multiple joint sets formulated on the basis of micromechanics, and implemented the same in finite-element analysis code to analyze rock structures under arbitrary loading and boundary conditions. This method enabled them to understand the behavior of a jointed rock mass, but also the deformation of joints during excavation of a large-scale cavern. This method was tested at Shiobara power station cavern in Japan and they found the results of models were in good agreement with the measured data. During the study it was noted that largest value of displacement is located at around the middle of the cavern, and displacement on the penstock side is much larger than on the tail race side and was according to the joint distributions in the rock mass. It was concluded that in a jointed rock mass, joint deformation is responsible for a large portion of the displacement.

Yoshida et al. (1995) formulated a micromechanics based continuum model for jointed rock mass. This MBC (micromechanics-based continuum) model reflects the effect of density, orientation and connectivity of joints as well as the property of joints. The constitutive equation is implemented into the FEM code for the analysis of problems with arbitrary geometry and boundary conditions. This method was applied to model a trial excavation of the reduced-scale cavern preceding the construction of the Kazunnogawa power station in Japan and found good agreement with the field results.

Zhu et al. (2008) analysed several caverns setup in China with 3 parallel caverns using FLAC-3D and formulated a method to study the safety of the underground caverns. An equation considering four basic factors were fitted for prediction of displacement at the key point on the high sidewalls of the powerhouse, on the basis of a large number of numerical simulations. The basic factors included rock deformation modulus, overburden depth of caverns, height of the powerhouse and the lateral pressure coefficient of the initial stress. Following equation was proposed for predicting the elasto-plastic displacement (U_{ep}) at the key point on the high sidewall of the powerhouse:

$$U_{ep} = h[a(1000 k \gamma H/E)^2 + b (1000 k \gamma H /E) + c] \times 10^{-3} \quad (2.8)$$

where,

h = Height of powerhouse, m

k = Lateral pressure (geo-stress) coefficient

γ = Bulk density of rock, kN/m^3

H = Lower overburden depth of the powerhouse (calculated from the cavern floor to ground surface), m

E = Deformation modulus of rock, Pa

a , b , and c are regression coefficients related to geometric structure and characteristics of the caverns

Zhu et al. (2010) modified equation 2.8 to include the ratio of the height of the powerhouse (h) to the net spacing (B) between the powerhouse and the transformer house. After a large

number of calculations for different schemes of cavern layout with different spacing, following displacement prediction equation was proposed:

$$U_{ep} = h[a(1000 k\gamma H/E)^2 + b(1000 k\gamma H/E) + c(B/H) + d] \times 10^{-3} \quad (2.9)$$

where,

B = Spacing between powerhouse and transformer hall cavern, m

Equation 2.9 was applied to predict the displacements at key points on the sidewalls for caverns of nine projects. Computation results were compared with numerical modelling or back-analysis results and the errors were less than 15%. A stability evaluation criteria of the surrounding rock mass based on the ratio (Θ) between the elasto-plastic (U_{ep}) and elastic displacement (U_e) to evaluate the extent of stability deterioration of surrounding rock was proposed and critical displacement ratio (Θ_c) equation was given as:

$$\Theta_c = 0.001403H - 0.01138E + 1.214375 \quad (2.10)$$

where,

H = Overburden depth, m

E = Rock mass modulus, GPa

Lee and Song (2003) highlighted the geotechnical work carried out in South Korea, particularly in mushroom and egg shaped caverns. Two-dimensional numerical analysis was carried out to determine the stability of the underground powerhouse cavern. The analysis used a coupled method that combines both the boundary element and finite element methods. In addition, a three-dimensional finite element method for continuum was used to examine effect of the discontinuities around the powerhouse cavern on the stress distribution. Their analysis concluded that an egg-shaped cross-section provides many advantages in structural stability.

Lee et al. (1995) investigated the effect of excavation-support sequences on the behaviour of underground crude oil storage caverns in a jointed rock mass using visco-plastic finite element model. They used back analysis based on the inverse method to evaluate the deformation modulus and the initial in-situ stress around caverns.

Lim and Kim (2003) carried out a comparative study on the stability analysis methods for underground pumped powerhouse cavern. For the stability analysis of the five underground powerhouses, finite element method was used. Visco-elastic finite element method with creep coefficient was used for stability analysis of Samrangjin pumped powerhouse cavern. Park et al. (2003) studied the stability of the cavern excavated in highly stress region (with high horizontal stress, where K_0 value was close to 3) using FLAC 2D Model. Results showed that stress exerted in the shotcrete at crown exceeds allowable value when 3rd bench (the lowest bench) is excavated for rock mass classes IV and V, and found tensile failure of shotcrete near the boundaries between benches for all classes of rock mass.

Lee et al. (2009) used a non-linear, three-dimensional finite element model to simulate the excavation of Baishan hydropower station in China. Drucker-Prager elastic-perfectly plastic material model was used for the simulation of rock mass, faults and the supporting structures. Material non-linearity was dealt with using an incremental technique. Displacement of the cavern wall was measured using three point rod extensometers. Field measurement results showed that the surrounding rock of cavern was stable with rock bolts and shotcrete as main supporting elements. Maximum deformation of cavern surface was less than 6mm and there was no further displacement after the cavern excavation was completed.

Ghorbani and Sharifzadeh (2009) assessed the long term stability of powerhouse cavern of Siah Bisheh pumped storage scheme in Iran under saturated condition using discontinuum modelling 3DEC. In this study, they used displacement measured from MPBX to carry out back analysis using univariate optimization algorithm. Their results showed increase in uplift pressures in discontinuities and local failures around the powerhouse after impounding of dam. Construction of a cut off curtain around the cavern was recommended. Same powerhouse was also modelled by Moosavi and Fattahpour (2009) using 3D finite difference models. Due to the closely spaced bedded sedimentary rocks (mostly quartzitic sandstones and reddish-brown and blackish siltstone of shaly appearance with low RQD index) around the cavern, the transversely isotropic elastic model was chosen to simulate the powerhouse cavern and related excavations. In addition, sheared and altered zones also

crossed the cavern axis. The results obtained from installed extensometers in sidewalls of powerhouse cavern showed good agreement with the displacements obtained from numerical modelling results. Safety factor for rock mass surrounding the caverns was determined using the induced stresses using Hoek and Brown Failure criteria. Results obtained from evaluation of safety factor showed some unstable zones around the cavern due to the existence of main sheared zone. Model results also showed an unstable zone between transformer and powerhouse caverns.

Wang and Zhu (2006) did bolting pattern optimisation for Yantan underground powerhouse in China using FLAC and FLAC-3D. Zhu and Chen (2009) studied the wall rock stability of the powerhouse of second extension project of Yantan using FLAC-3D and identified the zones of stress concentration and failure zones, and found that the cavern as a whole was stable.

Saran and Broch (2008) studied the stability of underground powerhouse cavern, transformer hall cavern, draft tube gate cavern, six bus tunnels and six draft tube tunnels of Xiaolangdi multi-purpose project in China using FLAC-3D. Both elastic and elasto-plastic analysis were carried out and following conclusions were made:

- Deformations of the powerhouse walls were much higher than that at the crown (H/W ratio is 2.34).
- Deformations of the transformer hall walls were almost same in both crown and side walls (H/W ratio is 1.19).
- Destressing of the rock mass was observed on downstream wall of the powerhouse extending upto 10 - 12m.
- After the excavation of bus tunnels and draft tubes, destressed zone increased on the downstream wall of powerhouse and destressed zone on upstream wall remained same.

Zhu and Zhu (2013) used discontinuum software 3DEC to analyse stability of the crown of cavern at Baihetan hydropower project, China. They studied stress induced failure of the crown due to stress localisation effect due to nearby shear zone. They also identified the

potential wedges formed by discontinuities and designed the support system based on results of the model.

Moghadam et al. (2013) studied the time dependent behaviour of underground caverns excavated in rock salt considering creep, dilatancy and failure. An elasto-visco-plastic constitutive model was utilized to describe dilatancy, short term failure as well as long term failure during transient and steady state creep of rock salt. Constitutive model was employed in a finite element code to simulate the stress variation and ground movement during creep of rock salt around the cavern within the framework of large deformations.

Xu et al. (2015) modelled the behaviour of rock mass containing an interlayer shear weakness zone in an underground cavern site. They used 3D continuum model with an equivalent continuum approach, including a rock-soil composite material model, and found it suitable for describing the behaviour of rock mass containing discontinuities.

Zhang et al. (2016) analysed the stability of the blocks formed by joints using 3DEC during the construction of Shenzhen pumped storage caverns in China. Joints mapped during pilot tunnel excavation were updated in the model after each excavation step and potentially unstable blocks in the next excavation step were identified and designed the support requirement accordingly.

Wu et al. (2016) conducted extensive rock mechanics investigations in the underground caverns of Jinping hydropower station in China. They studied the deformation and failure characteristics of the surrounding rock mass and stress characteristics of anchorage structures during the construction of the cavern. Layered rock mass composite model, LRCM was used to study the rock mass behaviour and response of support system. Model was able to consider the failure patterns of rock mass and joint planes to describe the anisotropic features of deformation and strength variations in the rock mass, and to simulate the progressive failure of rock mass induced by deformation.

Ma et al. (2016) conducted stability analysis of oil storage caverns by integrating numerical modelling and micro seismic monitoring. A numerical method called Continuous–Discontinuous Element Method (CDEM) was applied to simulate micro-cracks under excavation-induced unloading conditions. Microseismic (MS) monitoring system was

employed to monitor real time MS events during construction of storage caverns. Numerical results were validated using the monitoring data from the MS monitoring system. They found that the integrated method was useful in capturing micro cracks in underground storage caverns.

Xiao et al. (2016) studied stress-structure controlled collapse of surrounding rock mass during the construction of Baihetan hydropower station, China. An in-situ experiment involving microseismic monitoring was carried out in the powerhouse cavern and consistent set of results were obtained. They concluded that tensile fracturing is the rock mass fracturing mechanism that is most active during the process of evolution of stress structure controlled collapse.

2.8 INDIAN RESEARCH EXPERIENCES IN CAVERN RELATED STUDIES

In depth investigative and performance monitoring studies were carried out during the construction of Nathpa Jhkari Power Project in Himachal Pradesh, India. Underground powerhouse cavern [20m (W) x 49m (H) x 216m (L)] was investigated by Bhasin et al. (1996) using updated Q System (empirical) and analysed with 2D discontinuum model, UDEC-BB (which incorporates Barton-Bandis non-linear joint behaviour model). Model results were compared with the multi-point borehole extensometer results obtained during the instrumentation studies at the cavern. The results of deformation measurements indicated that the displacements in the periphery of the arch and in the deeper sections of the rock mass are similar to those predicted through the empirical and numerical approaches.

Dasgupta et al. (1995a, 1995b) used 3D discontinuum models using 3DEC to investigate the distress condition at the powerhouse of Sardar Sarovar project after cracks appeared on the walls of the cavern and inside the bus ducts. Horizontal major principal stress along the longitudinal axis of the cavern was found to be 3 times the vertical stress and intermediate principal stress across the cavern was 1.4 times the vertical stress. Narrow shear zones were explicitly modelled in 3DEC. Movement of the wedge was analysed and cable bolts were recommended as additional supports.

Dasgupta et al. (1999) used numerical modelling and instrumentation data as the basis for design of powerhouse cavern at Tehri hydroelectric project, Uttarakhand. A combination of two and three dimensional modeling was used in order to arrive at an effective and optimized support design. A two-dimensional analysis using FLAC was carried out to design a pattern of rock bolt support system and shear zones and major shear planes were modelled using 3DEC to advice on additional support.

Varadarajan et al. (2001) carried out finite element analysis of powerhouse cavern of Nathpa Jhakri project using computer code DSC-SST-2D developed by Desai (1997) with the constitutive model based on DSC. The procedure proposed by Ramamurthy (1993, 2001) to determine the strength and the Young's modulus of the jointed rock mass from the intact rock properties was suitably adopted to determine the material parameters for the constitutive model. They observed higher movements of the wall around mid-height of the cavern wall.

Finite element analysis of underground caverns of Koyna hydroelectric project was carried out by Dhawan et al. (2002). Four caverns, Machine hall [20.6m (W) x 50.14m (H) x 145m (L)], Valve house [(7m (W) x 13.15m (H) x 145m (L)], Transformer hall [20m (W) x 23.5m (H) x 173m (L)] and Collection gallery [10.8m (W) x 10.6m (H) x 173m (L)] at a depth of 160m were analysed. These caverns are located in amygdaloidal basalt comprising of horizontal and vertical brecciated rock horizons, at several locations. Finite element software Solvia 90, developed by Solvia Engineering AB, Sweden, was used for the analysis. Drucker-Prager failure criteria was adopted as the failure criteria in the model. They found that 3D elasto-plastic FEM analysis results closely matched with the field deformation observations for the nonhomogeneous rock mass with weak zones compared to the 2D modelling results. It was also observed that in multi-stage excavation, stresses at the end of a partial stage are higher than those occurring at the end of the complete excavation.

Sitharam and Lata (2002) used equivalent continuum method in FLAC and FLAC3D and analysed the powerhouse cavern of Nathpa Jhakri Project and found good agreement with the measured instrumentation data.

Samadhiya et al. (2004) developed an approach for analysis of caverns in jointed rock mass and shear zone and applied the method for the analysis of cavern at Sardar Sarovar Project, Gujarat. Shear zones were modelled using ASARM (Analysis of Stresses in Anisotropic Rock Masses). Elastic constitutive equations based on equivalent material approach were used to simulate the overall behaviour of the jointed rock mass. They found that stress concentration at the crown is much higher than in the sidewalls. Displacement in the sidewalls was much higher than the displacement at the crown.

Nair and Sripad (2012) studied the behaviour of powerhouse and transformer hall cavern of Tapovan Vishnugad hydroelectric project in Uttarakhand. They used 3D discontinuum modelling with 3DEC and the effect of a shear zone and biotite band behaviour on the stability of the cavern was studied. They recommended to install cable bolts in the pillar between the bus ducts.

Bhandari et al. (2016) carried out 3D analysis of two caverns, eight tunnels, and four shafts with different dimensions using FLAC-3D. Isotropic behaviour of relatively weak rock mass was modelled using Mohr-Coulomb model and anisotropic behaviour of schistose rock mass characterised by discontinuities was modelled using ubiquitous joint model. Trend of displacement with progress of excavation was also studied to establish the stability of caverns.

Various research studies related to cavern were briefly reviewed and presented. Review covered recent development in rock mass classification, major underground caverns in India, numerical modelling and other studies and research related to Indian caverns. It was found that detailed instrumentation to study the behaviour of caverns has not been carried out, particularly in the caverns in Himalayas. Stress distribution in the pillar between two caverns and effect of intermediate principal stresses has not been dealt with in detail. Instrumentation done during the construction of the cavern, in all cases was limited and was not continued during post excavation period. Orientation of the cavern with respect to principal stresses was also not covered in detail. Considering the lacunae in the so far available studies, an attempt is made in this research study to look into the following aspects:

- Study the behaviour of cavern during entire cycle of excavation and continue the monitoring during post excavation period.
- Study the effect of intermediate principal stress on stress distribution in pillar and abutment.
- Effect of orientation of the cavern on stress and displacement.

INVESTIGATIONS

The purpose of research study is to assess the behaviour of caverns and the surrounding rock mass in Himalayas.

Investigations were carried out with the following objectives:

- To study the deformational behaviour of crown of the cavern.
- To study the behaviour of side walls of the cavern.
- To study the effectiveness of rock bolts.
- To assess the influence of excavation of main cavern on the cross tunnels.
- To simulate the behaviour of the cavern in jointed rock mass using 3D Distinct Element Modelling and 3D Continuum Modelling, and compare the results with field observations.

The study was carried out in two phases:

1. Field Investigations
2. Numerical Modelling

3.1 FIELD INVESTIGATIONS

For this study, two large underground caverns at Tala Hydroelectric Project, Bhutan, situated in lower Himalayas were chosen. Field investigations were conducted in powerhouse cavern, transformer hall cavern and interconnecting tunnels from the beginning of the excavation. Information about geology of the area and the details of in-situ stresses were generated at the beginning of the excavation.

Following field investigations were conducted to generate geotechnical parameters:

- Collection of rock samples for determining physico-mechanical properties in the laboratory, as per ISRM standards.
- Monitoring the behaviour of surrounding rock mass using geotechnical instruments during each stage of excavation.

3.1.1 Description of the Site

There are many large underground caverns in Himalayas under construction. In order to study the stability issues of large caverns, a detailed field instrumentation programme was taken up at two caverns in Himalayas. Instrumentation studies were carried out at

caverns of Powerhouse complex of Tala Hydroelectric Project, Bhutan. Tala Hydroelectric Project is of 1020 MW capacity run of the river scheme in Bhutan on river Wangchu in Chukha Dzongkagh of Western Bhutan, immediately downstream of Chukha Hydroelectric Project (Fig.3.1).

Fig. 3.1 Location of Chukha Dzongkagh (CartoGIS, College of Asia and the Pacific, The Australian National University)

This project utilizes 861.5m of head available from Chukha downstream to Tala powerhouse. Main components of the project consist of a 92m high and 130m long concrete gravity dam located at Wangkha, about 3km downstream of Chukha powerhouse, an underground desilting complex comprising of three chambers (three intakes, each of 250m long, 13.9m wide and 18.5m high), 23km long and 6.8m diameter modified horse shoe shaped head race tunnel (with 5 adits) terminating in a 178m deep restricted orifice type surge shaft with a diameter of 15m/12m, two pressure shafts of 1.1km long and 4m diameter each and an underground powerhouse with powerhouse cavern of 206.4m x 20.4m x 44.5m dimension to house six generating units, each of 175MW, located on right bank of Wangchu river. Transformers and switchgears are also located in an underground cavern of 191m x 16m x 24.5m dimension, 40m downstream of powerhouse cavern. Water is taken back to river through a 7.75m

diameter horseshoe shaped, 3.1km long tail race tunnel. Location of dam site and powerhouse complex are shown in Figs. 3.2 and 3.3 respectively.

Fig. 3.2 Location of dam site, Tala Hydroelectric Project, Bhutan

Fig. 3.3 Location of powerhouse site, Tala Hydroelectric Project, Bhutan

The project is divided into five packages for effectively distributing the construction activities. Outline of the five packages (C1 to C5) is shown in Fig. 3.4. Plan depicting the caverns and tunnels in the powerhouse area is shown in Fig. 3.5.

Key Plan (not to scale)

3.1.2 Investigations in Powerhouse Complex

Powerhouse complex consists of powerhouse cavern, transformer hall cavern, bus ducts, pressure shaft manifolds, TRT manifolds, drainage galleries and other connecting tunnels. Salient features of powerhouse complex are as follows:

Powerhouse Cavern

a. Length	:	206.4m
b. Width	:	20.4m
c. Height	:	44.5m
d. Crown Elevation	:	538m
e. Springing Level EL	:	533m
f. Service Bay EL	:	514.5m

Transformer Hall Cavern

a. Length	:	191m
b. Width	:	16m
c. Height	:	24.5m
d. Crown Elevation	:	539m
e. Floor EL	:	514.5m

Bus Ducts and other Tunnels

a. Bus Ducts	:	10m x 8.5m D shaped tunnel 3 nos.
b. Passage Tunnels	:	2 nos.
c. Pressure Shaft Manifolds	:	6 nos.
d. TRT Manifolds	:	6 nos.

Powerhouse and transformer hall caverns are separated by a pillar of 40m thickness. Cross section of the powerhouse complex showing the dimensions of various components are shown in Fig. 3.6.

Vertical positions in the cavern are denoted by actual elevation (EL) and the horizontal positions along the length of cavern are denoted by reduced distance (RD). RD-0 refers to starting point of the corresponding cavern. RD-0 in transformer hall corresponds to RD-15.4 in powerhouse cavern as the end point of both the caverns (RD-206 of powerhouse and RD-191 of transformer hall) are aligned.

Fig. 3.6 Cross section of powerhouse complex, Tala Hydroelectric Project

Monitoring was carried out using various instruments in powerhouse cavern, transformer hall cavern in the following stages:

1. **Measurement of axial load on the rock bolts in the crown:** Axial loads on the rock bolts in the crown were monitored using Vibrating Wire Load Cells. Vibrating wire load cells of 40t capacity were installed at RD-15, RD-80, RD-130 and RD-150 of powerhouse cavern and RD-14, RD-59, RD-114 and RD-156 of transformer hall cavern. Load cell data collected was used for assessing adequate capacity of rock bolts in the crown and the behaviour of rock bolts with the excavation of crown.
2. **Measurement of displacements at various horizons in the crown of cavern:** In the crown of powerhouse cavern, Magnetic Ring Multi Point Borehole Extensometers (MRMPBX) of 20m length were installed at RD-15, RD-80, RD-130 and RD-150 of powerhouse cavern, and RD-14, RD-59, RD-114 and RD-156 of transformer hall cavern. Displacement data collected at various horizons in the crown was used to assess the joint opening and the overall bolt length required.
3. **Measurement of axial load in steel ribs in the crown:** Steel ribs of ISMB:350mm x 140mm sections were used in powerhouse cavern and ISMB: 300mm x 140mm section were used in transformer hall as final support in the crown. Axial load on the ribs was monitored using the solid load cells of 100t

capacity at EL-533. Load cells were used at six sections in powerhouse cavern, and at each section one load cell was installed on downstream side and one on upstream side. Load cell data was used to ascertain the efficacy of steel rib supports in the crown.

4. **Measurement of pore water pressure in the crown:** Pore water pressure in the surrounding rock mass was monitored using Vibrating Wire Piezometers of 7.0MPa capacity. Piezometers were installed at RD-15, RD-80, RD-130 and RD-150 of powerhouse cavern. Piezometer data was utilised for assessing build-up of water pressure in the crown area.
5. **Measurement of load on rock bolts in the side walls:** Development of load on 12m long Dywidag rock bolts in the side walls of powerhouse cavern and 8m long Dywidag rock bolts in side walls of transformer hall was measured using Vibrating Wire Anchor Load Cells. Load cell data was used to assess the efficacy of Dywidag rock bolts and to decide the adequacy of support requirements in side walls. Load cells were installed on the rock bolts at EL-525, EL-520, EL-515 and EL-506 at RD-15, RD-65, RD-110 and RD-150 in the powerhouse cavern on both upstream and downstream walls. In transformer hall cavern, the load cells were installed at RD-14, RD-60, RD-114 and RD-156 at EL-532, EL-525, and EL-520 on both walls. Load cell data was recorded with the progress of benching in the cavern.
6. **Measurement of convergence of side walls:** Convergence in the side walls of cavern was monitored using reflective targets with Total Station. Total Station, Leica TDA 5005, with angular accuracy of 0.5s was used for this purpose. Cumulative convergence was measured with the progress of cavern benches. Convergence was measured at RD-15, RD-65, RD-110 and RD-150 at elevations of EL-525, EL-520, EL-515 and EL-506 in powerhouse cavern and RD-60 at EL-531, RD-14, RD-60, RD-114 and RD-155 at EL-525 and EL-520 of transformer hall cavern. Convergence measurement was continued with benching in the cavern, and data was used for assessing the stability of cavern and calculating the strain values.
7. **Measurement of strain along the length of rock bolts:** Strains developing in the rock bolt along the length were measured using Rock Bolt Stress Meter,

also known as instrumented bolt. Instrumented bolts were installed at EL-506 on both upstream and downstream wall at RD-65, RD-110, RD-150 and at EL-515 (RD-140 and RD-150) of powerhouse cavern. Data from instrumented bolts was used to assess the distribution of strains along the length of rock bolts.

8. **Measurement of pore water pressure inside walls:** Pore water pressure in the surrounding rock mass was monitored using Vibrating Wire Piezometers of 7.0MPa capacity. Piezometers were installed at EL-525, EL-520, EL-515 and EL-506 at RD-15, RD-65, RD-110 and RD-150 in the powerhouse cavern on both upstream and downstream walls.

3.1.2.1 Laboratory testing and estimation of rock mass parameters

Laboratory testing was carried out by National Institute of Rock Mechanics (NIRM), Bengaluru, where the author is employed. Author was also part of the team and selected the samples from the field and the testing was carried out in his presence. Estimation of the rock mass properties was entirely done by the author.

Rock blocks of phyllitic quartzites and quartzites containing fractures and foliation planes were collected from the pilot tunnel of the powerhouse cavern. Cylindrical samples (BX and NX size) were prepared from the blocks by diamond drilling in the laboratory. Core samples were cut to the required length using rock cutting machine and the loading faces of samples were polished using an automatic surface grinder. Length to diameter ratio of 2.5 to 3.0 was maintained for all the tests. Following tests were conducted at the laboratory:

1. Uniaxial compression test.
2. Triaxial compression test.
3. Normal and shear tests on jointed rock.

Summary of the test results are shown in Table 3.1. Some of the properties could not be determined in the laboratory as sample preparation of quartzite from this site as per ISRM standard was difficult.

Table 3.1 Summary of laboratory test results

Property	Phyllitic Quartzite		Quartzite	
	Dry	Saturated	Dry	Saturated
Density, kg/m ³	2650	2650	-	-
Uniaxial Compressive Strength, MPa	63.17	51.90	-	-
Young's Modulus, GPa	18.35	12.93	70.6	61.24
Poisson's Ratio	0.35	0.36	0.18	0.19
Cohesion, MPa	18.56	15.71	-	-
Friction Angle, degrees	28.86	28.33	-	-
Hoek and Brown constant, m _i	4.18	4.49	-	-
Joint Normal Stiffness, GPa/m	10.4			
Joint Shear Stiffness, GPa/m	0.97			
Joint Cohesion, MPa	0			
Joint Friction Angle, degrees	25			

3.1.2.2 Geology of powerhouse complex

Geological investigations while excavating the caverns were done by geologists at Tala project Bhutan and author was interacting with them on daily basis. Geotechnical investigations while excavating the caverns was done by the author.

Powerhouse complex is situated in a hillock with overburden ranging from 400 - 500m. The host rock is fresh and hard, with inter banded sequence of quartzite, phyllitic quartzite and amphibolite schist partings. These rocks are highly puckered and folded into tight synform and antiform. Major discontinuity features were mapped from the exploratory drift of 2m x 2m driven in N37°W-S37°E (N143° – N323°) direction along the crown of powerhouse cavern. In addition to the foliation, five more sets of joints were identified. General foliation trend was found to vary from N65°E-S65°W to N70°W-S70°E with 35° to 60° (N25°W to N20°E) dips. Average dip of the foliation is 45.5° and dip direction N357°. Details of major discontinuities are listed in Table 3.2 (Singh et al., 2002).

Plunge/Trend of the folded axis was recorded at RD-16 (25°/270°), RD-93 (18°/056°), RD-128 (10°/090°), RD-143 (15°/130°) and at RD-183 (10°/088°). Long axis of the

powerhouse in N37°W-S37°E direction is across the strike of foliation. Due to folding, the angle between the long axis of powerhouse and strike of formation varied from 150° to 55°. Average value of foliation and five joint sets as given in Table 3.2 were used for the pole projection and kinematic analysis as shown in Fig. 3.7. In total, 10 wedges (W) have been marked and listed in Appendix-1. Kinematic analysis was done using friction angle (ϕ) of 30°.

Table 3.2 Major discontinuities in powerhouse cavern

Sl. No.	Strike	Dip	*AD	*ADD	Spacing	Continuity	Nature
Foliation (F1)	N65°E-S65°W to N70°W-S70°E	35°-60° N25°W to N20°E	45.5°	357°	10cm - 3m	5 - 12m	RU
J1	N20°W-S20°E to N15°W-S15°E	40°-80° N70°E to N75°E	60°	072°	1m - 2m	2 - 5m	RU
J2	N-S to N30°E-S30°W	25°-80° W to N60°W	52.5°	285°	5cm - 2m	2 - 10m	RU
J3	N30°E-S30°W to N20°E-S20°W	30°-50° S60°E to S70°E	40°	115°	6cm - 20cm	2m	RP
J4	N50°W-S50°E to N30°W-S30°E	60°-70° S40°W to S60°W	65°	230°	10cm - 2m	2 - 5m	SP
J5	N80°E-S80°W to N70°W-S70°E	40°-70° S10°E to S20°W	55°	185°	20cm - 2m	2 - 5m	RP

*AD – Average Dip, *ADD – Average Dip Direction, RU -Rough Undulating, RP - Rough Planar, SP - Smooth Planar

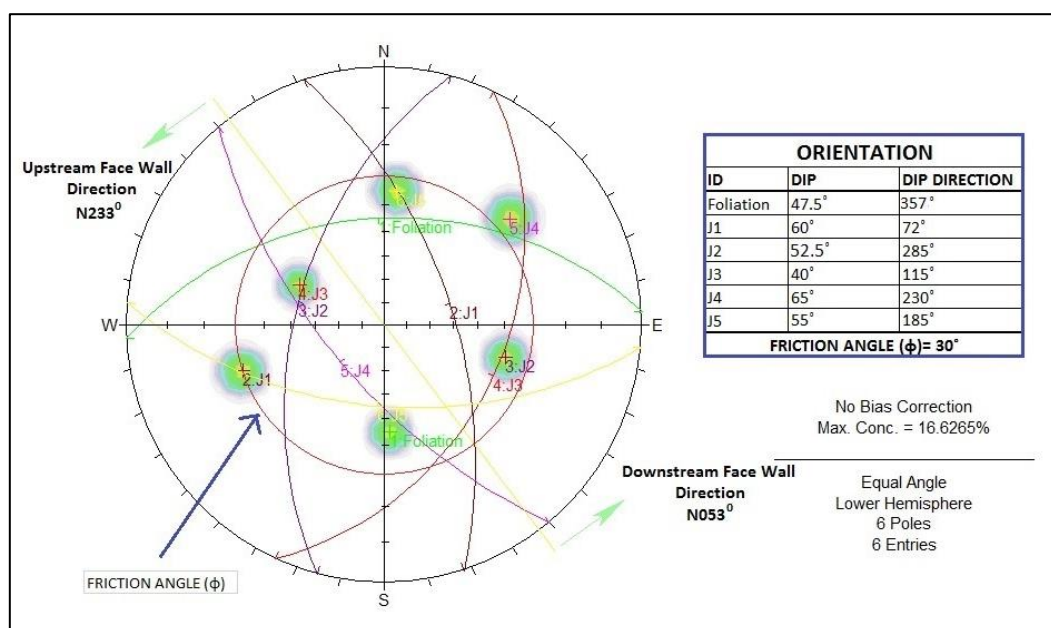

Fig. 3.7 Pole projection of joint sets of powerhouse cavern for kinematic analysis

Initially, mapping of powerhouse and transformer hall was carried out and the rock mass was found to be Fair to Good category, with 'Q' value ranging from 4.3 to 11 between RD-0 to RD-180, and around 2 between RD-180 and RD-206m. Estimated GSI values along powerhouse cavern drift were found to vary from 44 to 52, with fresh and hard quartzite and phyllitic quartzite constituting about 85-90% of the rock mass. Average GSI value of 50 was taken for further calculations.

3.1.2.3 In-situ stress

In-situ stress measurements were carried out by the team from National Institute of Rock Mechanics, Bengaluru, and the author witnessed the entire procedure at the site. Stress measurements were carried out at the powerhouse drift. The stress measurement indicated following stress regime:

Vertical stress = 10.9MPa (calculated from overburden weight)

Minimum horizontal stress = 9.5MPa (approximately normal to cavern axis)

Maximum horizontal stress = 14.2MPa (approximately parallel to cavern axis)

3.1.2.4 Excavation at powerhouse cavern

Excavation of powerhouse cavern started with 7m (W) x 7.5m (H) central gullet for the entire length of the cavern and later side slashing on either side to the full width of the cavern. The gullet was supported with 6m and 8m long rock bolts of 32mm diameter at 3m x 1.5m pattern and a layer of Steel Fibre Reinforced Shotcrete (SFRS) of 100mm.

During the crown excavation, there were roof collapses between RD-90 and RD-160. It was observed that, at most of the places, end anchors and bearing plates were intact and bolt shearing took place upto 3-4m distance into the roof and also rock mass between the bolts also failed. This indicated the separation of joints in the immediate roof (consistent with MPBX observation) and also the inadequate density of bolts. Subsequently, the crown of entire length of powerhouse cavern was supported with steel ribs of ISMB 350mm x 140mm section at 0.6m spacing, back filling with concrete and grouting.

After completion of the ribs and subsequent back filling, benching down of the powerhouse cavern started. First bench was started with excavation of central gullet of 6.5m width and 2.6m deep. The central gullet was advanced on either direction and

benches were formed on both upstream and downstream side. Benches were excavated with controlled blasting technique and by providing line drilling along the contact of wall rock. At any given time, a maximum of 9m span was exposed. The exposed wall was immediately shotcreted with 50mm thick plane shotcrete (M35 A10). On this surface, welded wire mesh of 100mm x 100mm x 5mm was fixed followed by installation of high strength Dywidag bolts of 12m long and 32mm/26.5mm diameter at 1.5m centre to centre, in a staggered manner. The Dywidag rock bolts of 26mm diameter had yield strength of 1,033MPa and tensile strength of 1,122MPa (Singh et al. 2003). The rock bolts were end anchored with resin capsules for initial 4m and rest was grouted with cement slurry. This was followed by two more layers (each 50mm) of shotcrete. Sequence of excavation of benches and the duration of excavation of each bench is shown in Fig. 3.8.

Fig. 3.8 Sequence and period of excavation at powerhouse cavern

Widths of central gullet and benches were varied to suit the geological conditions. From 6th bench and downwards, the benching was done between RD-60 and RD-206.4 only. Eleven benches were excavated upto EL-499.5. View of the powerhouse cavern after complete excavation is shown in Fig. 3.9.

Fig. 3.9 Powerhouse cavern after complete excavation, Tala Hydroelectric Project

3.1.2.5 Excavation of transformer hall

Transformer hall of 191m x 16m x 24.5m dimensions was excavated on the downstream side of powerhouse cavern in the power house complex. A rock pillar of 40m thickness was left between powerhouse and transformer hall. The EL of the crown was 539m, floor was 514.5m and springing level was at 535.5m.

Excavation of transformer hall started with excavation of the central gullet of 7.5m (W) x 7.5m (H). Central gullet was supported by SFRS and 6m long rock bolts of 32mm diameter with 1.5m x 1.5m pattern. This was followed by side slashing with SFRS of 150mm and rock bolts of 6m and 8m long, 32mm diameter at 1.25m x 1.25m pattern. Further, the entire cavern roof was supported with steel ribs of ISMB 300mm x 140mm section with back filling and contact grouting.

The benching operation in transformer hall started with the excavation of first bench from EL-533 to EL-530. The second bench was excavated from EL-530 to EL-527. The walls were supported with Dywidag bolts of 8m long and 32mm/26.5mm diameter in conjunction with wire mesh and plain shotcrete. The sequence of excavation of benches and the duration of excavation of each bench in transformer hall is shown in Fig. 3.10.

Fig. 3.10 Sequence and period of excavation at transformer hall cavern

3.1.2.6 Excavation of bus ducts

Bus ducts were excavated upto 10m initially from powerhouse side. The excavation of bus ducts which was earlier upto 10m from powerhouse side was continued from transformer hall side and excavation was completed.

3.1.3 Field Instrumentation

Various geotechnical instruments were installed by the author in powerhouse cavern, transformer hall cavern and bus ducts during various stages of construction. Section showing the location of various types of instruments is shown in Figs. 3.11 to 3.15.

Fig. 3.11 Section of the powerhouse cavern showing location of instruments

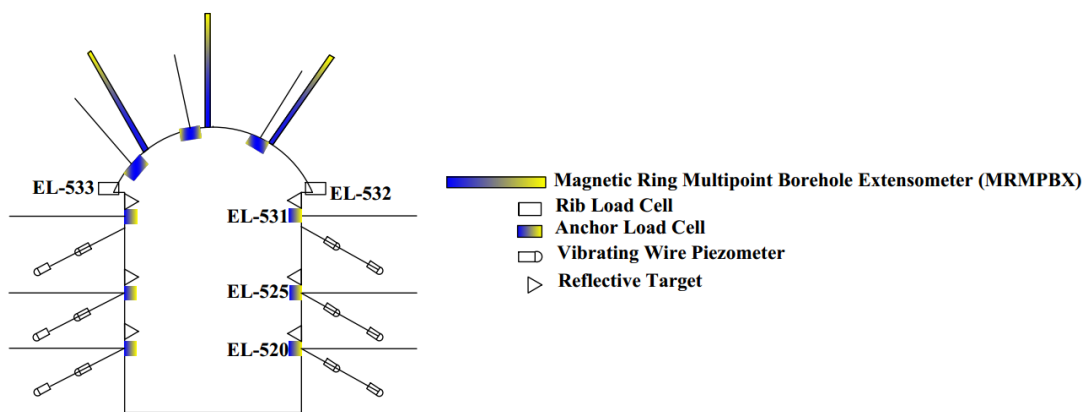

Fig. 3.12 Section of the transformer hall cavern showing location of instruments

Fig. 3.13 Longitudinal section of the powerhouse cavern showing location of instruments on upstream wall

Fig. 3.14 Longitudinal section of the powerhouse cavern showing location of instruments on downstream wall

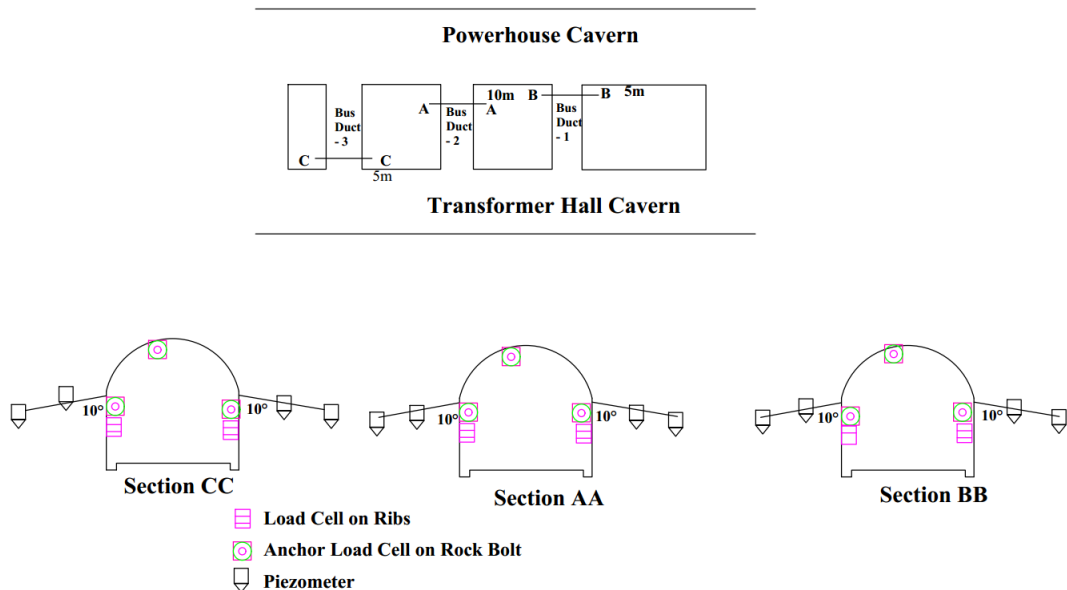

Fig. 3.15 Section of bus ducts showing the location of instruments

Monitoring details of the instruments are given below:

a. Monitoring at Powerhouse cavern

Displacement monitoring in surrounding rock mass	Crown: MRMPBX were installed in the crown at RD-15, RD-80, RD-130 and RD-150 at center, left and right side of crown. Instruments were regularly monitored till the installation of ribs in the cavern. Readings were taken manually.
Load on the rock bolts and ribs	Crown: Load cells were installed on the 8m long rock bolts at RD-15, 80, 90, 100 and 110 and were regularly monitored till the installation of the ribs in the crown. Walls: Load cells were installed at EL-525, 520, 515 and 506 at RD-15, 65, 110 and 150 on both walls and at few other selected locations. Load cells were monitored regularly. Ribs: Load Cells were put on the ribs at RD-18.5, RD-56.5, RD-126, RD-143.4 and RD-173.5 on upstream and downstream wall. Load on the ribs were regularly monitored.

Convergence of the side walls	Cumulative convergence of the side walls was monitored using reflective targets and total station. Reflective targets were installed at RD-15 at EL-525 & 520 and at RD-65, 110, and 150 at EL-525, 520, 515 and 506. Since no physical access was required for their monitoring, the convergence was monitored regularly during the entire excavation of the cavern.
Strains along the length of rock bolts	Strains along the length of rock bolts were monitored using vibrating wire instrumented bolts. Instrumented bolts were installed at EL-515 at RD-140 & 150 and at EL-506 at RD-65, 110 and 150. Strains were regularly monitored.
Pore water pressure	Pore water pressure in the surrounding rock mass was monitored with vibrating wire piezometers. Piezometers were installed at EL-525, 520, 515 and EL-506 at RD-15, 65, 110 and 150. Pore water pressure was monitored during various excavation stages.

b. Monitoring at Transformer hall cavern

Load on the rock bolts and ribs	<p>Crown: Load cells were installed on the rock bolts in the crown of the central gullet at RD-14, 60, 114 and 156.</p> <p>Ribs: Load cells were installed at RD-14, 70.6, 84.5, 113.2, 129.4 and 154.4 on both upstream and downstream side.</p> <p>Walls: At EL-532, load cells were installed at RD-13, 15, 80 and 155 on upstream side and at RD-80, 81 and 155 on downstream side. At EL-525, load cells were installed at RD-14, 60, 121 and 164 on upstream side and 113.5 and 154 on downstream wall. At EL-520, load cells were installed at RD-14, 58, 121 and 162 on</p>
---------------------------------	---

	upstream side and RD-13, 60, 114 and 162 on downstream wall. Load cells were regularly monitored.
Convergence of the side wall	Convergence of the side walls was measured using reflective targets and total station at EL-531, RD-60, EL-525 at RD-14, 60, 114 and 155, EL-520 at RD-14, 60, 121 and 155. Convergence was monitored regularly during the entire excavation of the cavern.
Pore water pressure	Piezometers were installed at EL-531 at RD-60 and RD-155 and at EL-525, at RD-60 and RD-162 on both walls of transformer hall. At each section, one piezometer was installed at a depth of 5m and one more piezometer was installed at a depth of 10m. Pore water pressure was monitored during various excavation stages.

c. Monitoring at bus ducts and connecting tunnels

Load on the rock bolts and ribs	<p>Ribs: Load cells were put on the ribs at RD-5 from powerhouse side in bus duct no.1, 10m from powerhouse side in bus duct no.2 and 5m from transformer hall side in bus duct no.3 and at RD-24.75 at passage no.1.</p> <p>Walls: Load cells were put on rock bolts at RD-5 on left wall in bus duct no.1, RD-10 left and right side crown in bus duct no.2, RD-35 at bus duct no.3 in the crown.</p>
Pore water pressure	Piezometers were installed on the side walls of bus ducts at the same sections, one at 5m depth and other at 10m depth.

3.1.4 Instrumentation and Installation

Instruments were installed and monitored by the author with the help of a colleague (both were stationed at the site) during the excavation of entire powerhouse complex. Analysis of the instrumentation data was also carried out simultaneously. Details of various monitoring instruments used in the field investigations and installation procedures are described below:

Monitoring of displacement

Multipoint borehole extensometers were used to monitor the displacements at various depths in the surrounding rock mass during various stages of excavation of the caverns. Anchors were placed at various depths at close intervals above and below the bolted horizon. The details and installation procedure are outlined below.

Multi-point borehole extensometers

There are various types of extensometers depending on different technologies. In this study, Magnetic ring multi point borehole extensometer (MRMPBX) were used.

Magnetic ring multi point borehole extensometer (MRMPBX)

MRMPBX was used to study displacement at various depths and joint separation in the roof and walls of the caverns. In this type of extensometer, anchors are magnetic rings that are placed at desired depths. Position of each anchor was measured with respect to the deepest anchor and distances obtained were used to determine the rock movement at various depths. An access pipe passes through the central hole of each anchor and is connected to the face plate anchored to the rock surface. Measurements were taken by lowering a probe through the access pipe to detect the depth of the magnetic anchor.

Installation: A NX size borehole (55mm diameter) was drilled upto a depth of 25m with Boomer machine. Borehole was flushed with compressed air and later cleaned with water to clear drill cuttings. The deepest anchor was attached to a hollow PVC pipe (access pipe) and pushed to deepest point in the borehole. Other anchors were put at required depths with the help of installation tool. Each anchor passed through the hollow pipe installed earlier and released at the required depth so that it is tightly anchored to the rock mass. Procedure was repeated till all the magnetic anchors were in place. Face plate was put at borehole collar so that hollow access pipe passed through the plate and excess length of tube was cut such that it matched with the reference

marking on the face plate. A sensor probe with graduated scale was put through the hollow PVC pipe and pushed inside by attaching additional graduated scales. Sensor probe detects each magnetic ring when it passes through the anchor with an audio and visual indicator on the readout unit. Reading of the graduated scale at that point was read against the reference mark on the face plate and exact position of anchor was noted. Procedure was repeated till all the magnetic sensors were sensed and the exact location of each anchor was noted as initial reading. Monitoring was done regularly and any relative movement between the anchors was determined by comparing the readings with the initial reading. Fig. 3.16 shows the MRMPBX with the readout unit.

Fig. 3.16 MRMPBX with the readout unit

Measurement of load in rock bolts

Axial loads on the rock bolts were measured using anchor load cell of 50t capacity. Similarly, the axial load on the steel ribs was measured using solid load cell of 100t capacity. Both types of load cells were of vibrating wire type. Load cell was installed immediately after the rock bolt or steel ribs at the specified location was put, and was monitored regularly with the excavation of the cavern. Details of load cell and installation procedure are outlined below.

Anchor load cell

Vibrating wire anchor load cells were used for the measurement of loads in rock bolts. Anchor load cell in this investigation consisted of four vibrating wire strain gauges mounted parallel to the cell axis of symmetry and equally spaced. Each vibrating wire assembly consisted of a tensioned wire clamped at both ends. Located at the mid-section of the wire is a coil/magnet. When an electrical pulse was supplied to the coil/magnet, the wire oscillated at its natural resonant frequency. Oscillations of the wire through the magnetic field induced an alternating current in the coil, detected by a readout unit. Readout unit displayed the frequency in Hz after converting the sinusoidal alternating voltage to frequency. Each load cell came with heavy gauge multicore and PVC sheathed cable.

Load cells were installed immediately after installation of rock bolts. It was made sure that sufficient length of rock bolt was projecting outside and rock mass around the rock bolt is even. A face plate made of steel slightly bigger than the load cell cross section was put through the bolt and held against the rock. Load cell was then inserted through the bolt and reaction plate of same dimension as face plate was put on top of the load cell. Later, nut was put on top of that and tightened. After tightening, initial reading of the load cell was noted down. Subsequently, required tension was applied to the rock bolt with the help of torque meter and change in load was noted down using the read out unit. The design concept of anchor load cell is shown in Fig.3.17.

Fig. 3.17 Schematic diagram of anchor load cell with rock bolt

Fig. 3.18 shows the anchor load cell with the readout unit and the anchor load cell installed on the rock bolt at powerhouse cavern is shown in Fig. 3.19. Fig. 3.20 shows rib load cell installed at the crown of powerhouse. A typical output monitoring is shown in Fig. 3.21.

Fig. 3.18 Anchor load cell with readout unit

Fig. 3.19 Anchor load cell installed on rock bolt at powerhouse cavern

Fig. 3.20 Load cell on the steel rib at crown of powerhouse

Fig. 3.21 Monitoring of load cells at walls of the cavern

Monitoring of convergence of side walls

Convergence between main walls of the cavern was monitored using geodetic technique, with combination of reflective paper targets and total station. Convergence of the walls was measured on a regular basis during all stages of excavation of the cavern. The procedure is described below.

Reflective targets and total station

Wall convergence of the caverns was measured using reflective targets with Total Station. Total Station, Leica TDA 5005, with an angular accuracy of 0.5s was used for this purpose. Reflective targets were fixed on a plate which was held by a rod grouted

into the wall to a depth of 1m. Stations were fixed opposite to each other on upstream and downstream walls. Instrument was set on the ground and levelled and the distances between the reflective targets were measured using the total station. Cumulative convergence of the two walls was computed based on the distances between the points at different stages of excavation. Fig. 3.22 shows the Total Station TDA 5005 with the reflective targets used at the cavern. A program in the Total Station called Tie-Distance was used for measuring the convergence. Monitoring of the reflective targets using Total Station is shown in Fig. 3.23.

Fig. 3.22 Total station TDA 5005 with reflective targets

Fig. 3.23 Measuring the convergence using Total Station TDA 5005

Monitoring of pore water pressure

Pore water pressure in the rock mass was measured using vibrating wire piezometers.

Vibrating wire piezometers

Piezometer is an instrument used to measure the pore water pressure. VW piezometer converts water pressure to a frequency signal through a diaphragm, a tensioned steel wire, and an electromagnetic coil. Piezometer is designed so that a change in pressure on the diaphragm causes a change in tension of the wire. When excited by the electromagnetic coil, the wire vibrates at its natural frequency. Vibration of the wire in the proximity of coil generates a frequency signal that is transmitted to the readout device. The readout device processes the signal, applies calibration factors, and displays a reading in the required engineering unit. Fig. 3.24 shows vibrating wire piezometer and schematic diagram of installation. Monitoring of the piezometer at the powerhouse cavern is shown in Fig. 3.25.

Installation: Borehole of 38mm diameter was drilled beyond the proposed piezometer location by about 15cm and cleaned thoroughly with compressed air and water. The bottom 15cm was then filled with clean fine sand and piezometer was lowered and put in place and clean sand was placed all around it for about 15cm to form collection zone. Above this, a layer of bentonite was put followed by grouting of the entire hole. Initial reading was taken after the grout was set. Reading in frequency was converted to piezometric pressure using the formula given in the calibration sheet for each instrument.

Fig. 3.24 Vibrating wire piezometer

Fig. 3.25 Monitoring of piezometers at walls of the cavern

Vibrating wire rock bolt stress meter/instrumented bolt

Vibrating wire rock bolt stress meter is an instrumented bolt which measures the strain on rock bolt, which is then converted to the stress. It consists of rock bolt anchor, sensor head and signal cable. Vibrating wire strain gauges fitted inside the rock bolt at 1m interval detects stress caused by strata movement, relaxation, etc. Vibrating wire gauges were pre-tensioned to about 2000Hz. When displacements perpendicular to the rock bolt occur, the gauges detect and output the corresponding frequency signal. Signal is transmitted to the VW readout unit. Fig. 3.26 shows the instrumented bolt.

Fig. 3.26 Vibrating wire instrumented bolt

Installation: Instrumented bolt looks like normal rock bolt and sensor head with signal cable from all the sensors are projected from one end. It was installed in the same way as normal rock bolt. Sensors at various depths along the bolt are identified by color codes and frequency was measured with the readout unit and converted to strain and stress using the formula given in the calibration sheet for each instrumented bolt.

3.2 NUMERICAL MODELLING

In this stage of the study, behaviour of the powerhouse cavern, transformer hall cavern and cross tunnels were studied at various stages of excavation and supporting using 3D numerical models. Three dimensional stress analysis of the caverns was carried out by the author using 3D Discontinuum software 3DEC (Anon, 2010) and 3D continuum software FLAC-3D (Anon, 2015).

3.2.1 3D Discontinuum Model using 3DEC

A 3D discontinuum model was constructed with the actual geometry of the powerhouse cavern, transformer hall cavern, cross tunnels (bus ducts and passages) and peripheral tunnels (penstock manifolds and tail race tunnel manifolds). Major joints crossing the powerhouse cavern at the center of the cavern were mapped and incorporated into the model. Details of joints mapped and used in the model are given in Appendix-1. Model size of 250m across the cavern axis (X-direction), 350m along the length of cavern axis (Y direction) and 200m in the vertical direction (Z-direction) was taken. In the model, 500m overburden load was applied. From the crown of the cavern 112m was modelled and the balance 388m of overburden load was applied on the top boundary of the model. Boundary in X-direction was at a distance of 12.25 times the biggest cavern width (20.4m) and in Y-direction it was at a distance of 17.15 times the cavern width. Thus boundaries were placed at sufficient distances away from the excavation in order to prevent the end constraint effect. Model was discretised into zones using 3DEC's inbuilt mesher. Zone size of 1m was chosen in the immediate wall and gradually increased outwards so that the ratio between immediate edges does not exceed 3. A typical 3D view of the model developed using 3DEC is shown in Figs. 3.27.

Fig. 3.27 Perspective view of powerhouse complex, Tala Hydroelectric Project

Rock mass properties for the model were estimated based on the procedure outlined by Hoek et al. (2002) and Hoek and Diederichs (2006), using the laboratory test data and the rock mass classification parameters. These rock mass parameters were further used in the 3D modelling. Estimated rock mass parameters with disturbance factor (D) of zero (undisturbed) and 0.8 (disturbed zone due to blasting) are listed in Table 3.3.

Table 3.3 Estimated rock mass parameters in powerhouse complex

Property	Depth: 500m				Unit
	Dry Condition		Saturated Condition		
	D=0	D=0.8	D=0	D=0.8	
Hoek – Brown Classification Parameters					
Uniaxial Compressive Strength (UCS)	63	63	51.9	51.9	MPa
GSI	50	50	50	50	
m_i	4.18	4.18	4.49	4.49

Density	2650	2650	2650	2650	kg/m ³

Geo-mechanical properties were assigned to major joints (fractures) in the 3DEC Model and properties assigned are listed in Table 3.4.

Table 3.4 Joint Properties in 3DEC Model

Property	Major Joints	Shear Joints
Joint Normal Stiffness	40 GPa/m	10 GPa/m
Joint Shear Stiffness	10 GPa/m	2 GPa/m
Joint Cohesion	0	0.003 MPa
Joint Friction angle	36	25
Joint Tensile Strength	0	0

Mohr Coulomb elasto-plastic model was used for simulation of excavation. Measured in-situ stresses were applied in the model and model was brought to equilibrium. Excavation in the model was done as per the actual excavation sequence followed during the excavation of the cavern. Supports were applied in the model after allowing initial deformation of 30% to occur (Hoek, 2001). Steel ribs in the crown were modelled with beam elements. Shotcrete was modelled as liner elements in 3DEC and rock bolts were modelled as reinforcing elements, which act at the intersection of joints. Properties of support elements used in the model are given in Tables 3.5 to 3.7.

Table 3.5 Rock Bolt Properties used in 3DEC (Local reinforcement *axial* command)

Property	8m long 32mm dia Bolt Fe500	12m long 32mm dia Dywidag Bolt	12m long 26.5mm dia Dywidag Bolt
Area of Bolt	8.04E-04 m ²	8.04E-04 m ²	5.51E-04 m ²
Axial Stiffness	5.33 GPa/m	5.54 GPa/m	3.67 GPa/m
½ Active Length	0.0349 m	0.0342 m	0.0317 m

Cohesive shear strength	0	0
Friction angle	30 deg	30 deg
Normal Stiffness, kn	10000 MPa/m	10000 MPa/m
Shear Stiffness, ks	10000 MPa/m	10000 MPa/m
Tensile Strength	0	0

Model was again brought to equilibrium till the unbalanced forces in the model were reduced to 1E-3 of its initial value (Anon, 2010). This was followed by next excavation step and continued till all the benches and tunnels were excavated in the model. Excavation sequence followed in the model is shown in Fig. 3.28. Typical size of the model after the in-situ stresses was 1.27GB and final model size was 1.37GB. Model was run on HP Z840 Workstation (Intel Xeon CPU E5-2687W v3 @3.10GHz) running on Windows 10 with 64GB RAM. Each model run took 3 days and 8 hrs for completion.

Fig. 3.28 Excavation sequence adopted in the 3D Model

Model assumptions

Following are the assumptions made in the modelling:

1. A constant depth cover of 500m was used.
2. Since in-situ stresses were determined on the assumption that vertical stress is one of the principal stresses, same assumption was followed in the model also.
3. GSI value of 50 was used and derived rock mass parameters for saturated conditions were used in the model.
4. Only major joints intersecting the powerhouse crown were explicitly modelled in 3DEC model.
5. Model was considered to be elasto-plastic with yielding of rock mass at failure.
6. Various stages of excavation were done as per the overall bench details. For example each bench is excavated at once.

7. Excavation was simultaneously done in powerhouse and transformer hall cavern.
8. Supports were installed after allowing 30% of deformation after the excavation in the model.
9. Compressive stresses are negative and tensile stresses are positive.
10. Equivalent stress of overburden load was applied on top of the model and bottom boundary was fixed and sides were given roller boundaries. Boundary conditions are shown in Fig. 3.29.

Fig. 3.29 Boundary conditions in the 3D model

Failure criteria for calculation of strength to stress ratio

The original Hoek and Brown yield criteria is an empirical criterion developed through curve-fitting of triaxial test data. However, the criterion was revised substantially based on the large scale field test on different types of rock mass. Currently, this criterion is the most widely used failure criterion for estimating the strength of jointed rock masses. In case of Himalayan region, it was observed that intermediate stresses also play an important role in influencing the stability of the underground structures. As Tala powerhouse is located in the active Himalayan tectonics, it was found necessary to consider all the three principal stresses in the analyses. Numerous extensions of modified Hoek and Brown yield criterion to 3D space have been proposed by various

researchers (Pan and Hudson, 1988; Priest and Hunt, 2005; Zhang and Zhu, 2007; Zhang, 2008; Melkounian et al., 2008). In this study, three dimensional Hoek and Brown yield criterion proposed by Melkounian et al. (2008) was used in the analysis of failure state of rock mass.

Output from the Model

3DEC has post processing terminal where all the results of the model can be accessed through an interactive terminal. Cross sections at any point can be taken in the model and the following output were available:

- Principal stress distribution (color scale)
- Normal stress contours in any plane (color scale)
- Shear stress contours in any plane (color scale)
- Stress tensor plot
- Displacement contours (Total, X-Displacement, Y-Displacement, Z-Displacement)
- Strain (color scale) (XX, YY, ZZ, XY and XZ strain)
- Displacement vector plot
- Joint normal stress, shear stress, normal displacement, shear displacement

3.2.2 3D Continuum Model using FLAC-3D

A 3D continuum model was constructed with the actual geometry of the powerhouse cavern, transformer hall cavern, cross tunnels (bus ducts and passages) and peripheral tunnels (penstock manifolds and tail race tunnel manifolds). Model sizes and boundary conditions were same as 3DEC model developed in this study. In the model, no discontinuities were modelled explicitly as the rock mass classification includes the influence of discontinuities and properties were estimated using laboratory and rock mass classification parameters. In the model, blasting zone of 2m was provided in the immediate vicinity of the excavation. Entire geometrical model was created in Rhinoceros-3D software (Anon, 2012) and model was taken to Kubrix software (Anon, 2014) for mesh generation. Mesh sizes were 1m in the blasting zone and increased gradually outwards keeping the ratio of adjacent edges of zone to less than 3. Mesh grid was imported to FLAC-3D and was available for run with all the excavation steps clearly identified as separate regions. A Typical model in FLAC-3D is shown in Fig.

3.30. Details of the caverns and tunnels modelled in FLAC-3D are shown in Figs. 3.31 and 3.32. In this case, same procedure of excavation and supporting was done as followed in the case of 3DEC model. The properties used for various support elements in FLAC-3D are listed in Tables 3.8 to 3.10

Fig. 3.30 3D continuum model of Tala powerhouse complex

Polar moment of inertia, J	1.38E-4 m ⁴

Mohr Coulomb elasto-plastic model was used for simulation of excavation. Measured in-situ stresses were applied in the model and model was brought to equilibrium. Excavation in the model was done as per the actual excavation sequence followed during the excavation of the cavern. Supports were applied in the model after allowing initial deformation of 30% to occur (Hoek, 2001). Steel ribs in the crown were modelled with beam elements, shotcrete was modelled as liner elements in FLAC-3D and rock bolts were modelled as cable elements. Model was again brought to equilibrium till the unbalanced forces in the model were reduced to 1E-3 of its initial value (Anon, 2010). This was followed by next excavation step and continued till all the benches and tunnels were excavated in the model.

In this case also, model at each stage of excavation was saved so that comparison between the excavation stages could be made or data pertaining to any individual excavation stage could be extracted during the analysis of model results.

Typical size of the model after imposing the in-situ stresses was 1.01GB and final model size was 1.28GB. Model was run on HP Z840 Workstation (Intel Xeon CPU E5-2687W v3 @3.10GHz) running on Windows 10 with 64GB RAM. Each model run took 14hrs.

Output from the model

FLAC-3D has post processing terminal where all the results of the model can be accessed through an interactive terminal. Cross sections at any point can be taken in the model and the following output were available:

- Principal stress distribution color scale
- Normal stress contours in any plane color scale
- Shear stress contours in any plane color scale
- Stress tensor plot
- Displacement contours (Total, X-Displacement, Y-Displacement, Z-Displacement)
- Strain color scale (XX, YY, ZZ, XY and XZ strain)
- Displacement vector plot
- Zone contour maps of principal stresses

Some of the typical outputs from the FLAC-3D model are presented in Figs. 3.33 to 3.38.

3.2.3 Basis of Analysis

Output from both 3DEC and FLAC-3D were available in the form of displacements (total displacement, and displacement in X, Y and Z direction) at each zone, all three principal stresses, normal stresses, shear stresses. In structural elements (bolts and shotcrete), normal and axial forces and stresses were also available. In addition, in 3DEC, normal and shear stresses in the joints, normal and shear displacements in the joints were also available. In this investigation since displacement and convergence data was mainly available, it was compared with the model results. All the output available from the model were of cumulative in nature and data pertaining to any excavation stage was extracted by the saved files of the model so that comparison could be made between successive excavation stages. Convergence stations at EL-525 were installed when the excavation of bench-4 was nearing completion. Therefore bench-4 displacements were taken as reference and cumulative convergence from the model at each stage was computed from data extracted at each excavation stage. Similarly, for EL-520 and EL-515, bench-6 and bench-7 results were taken as reference respectively. Principal stresses were used to estimate the strength of rock mass using 3D failure criteria and strength to stress ratio were plotted using FISH function in FLAC 3D. Strain in the walls of the cavern were also calculated using FISH function taking the displacement output from the model.

Stability of the caverns was assessed based on the comparison of displacement, strength to stress ratio and the strain distributions in the model coupled with physical observations in the caverns.

3.2.4 Parametric Study

Cavern orientation with respect to direction of major principal stress direction is one of the important parameters in cavern stability. Variation of stress distribution in the pillar between powerhouse and transformer hall and on the side abutments of cavern can influence the cavern behaviour and selection of appropriate supports. Parametric study was carried by varying the angle (Φ) between cavern axis and direction of major principal stress direction. Final FLAC-3D model, where there was close agreement with the measured data, was taken as the base model and alignment of the caverns were changed at an interval of 15° . Analysis was done for 12 orientations upto an angle of 165° as shown in Fig. 3.39.

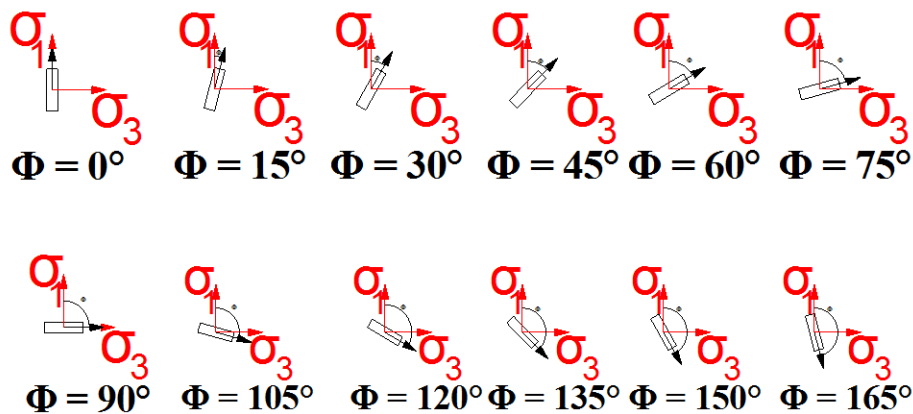

Fig. 3.39 Orientation of caverns with direction of maximum principal stress

In-situ stresses were resolved in the direction of new orientation and were applied in the model to simulate the effect of change in cavern orientation. Shear stresses were applied while investigating the effect of cavern orientation on cavern stability. Tables 3.11 to 3.17 give details of all the stresses (including the shear stresses). For orientations 15° and 105° the magnitudes of shear stress will be same but direction will be clock wise and anti-clock wise respectively. This is applicable to other directions also like 30° and 120° , 45° and 135° , 60° and 150° and 75° and 165° .

A database program was created in Microsoft Access-2013 and output from each model were extracted and taken into the database for further data extraction and analysis.

3.2.5 Sensitivity Analysis

Sensitivity analysis is defined as the study of how uncertainty in the output (dependent variable) of a model can be attributed to different sources of uncertainty in the model input (independent variable). It is a technique used to determine how different values of an independent variable impact a particular dependent variable under a given set of assumptions. This technique is used within specific boundaries that depend on one or more independent variables. In this study, local sensitivity analysis approach is used. Local sensitivity analysis is a one-at-a-time (OAT) technique. OAT techniques analyze the effect of one parameter on the final output at a time, keeping the other parameters fixed.

Sensitivity of the developed 3D model to changes in cohesion, friction angle, elastic and Poisson's ratio were tested by changing each parameter value in the range of -20% to 20% at a step of 5%. Sensitivity of the model was analysed using tornado diagrams.

RESULTS AND DISCUSSION

The results from field investigations and numerical modelling are analysed and presented in this chapter.

4.1 POWERHOUSE CAVERN

4.1.1 Movement at the Center of Crown

The movement of rock mass at different horizons above crown was monitored by Multiple Ring Magnetic Point Borehole Extensometers (MRMPBX). Cumulative data of MRMPBX observations at RD-15 center of the crown are shown in Fig. 4.1. The displacements noted at surface, 0.7m, 1.5m, 2.2m, 3m, 4.3m, 5.1m, 6m, 8m, 8.7m, 9.5m, 11.5m, 14.2m, 14.7m, 18m, 20m and 25.5m depths above crown are listed in Table 4.1 and depicted in Fig. 4.1. Displacements at various anchors within first 27 days were 3mm. During this period, side slashing at this location had not started. When the side slashing started at this location, the surface displacement increased to 20mm. A displacement of 8mm was observed at 0.7m depth, 2mm at 1.5m depth, clearly indicating separation of SFRS layer from the roof. After a period of 107 days, joint separation at the bolted horizon (8m) started, which further extended upto a depth of 9.5m. At this point, minor cracks started appearing on the surface of the crown. With further side slashing and with time, separation of joints at other horizons also started, as indicated by displacement recordings shown in Fig. 4.1.

		41	10	10	-3	12	2	2	10	5	8	-2	19	1	1	0	0	-1

After a period of 197 days, surface displacement recorded was 115mm with 20-74mm displacements recorded between 0.7m and 9.5m horizons, indicating development of cracks in the range of 2-41mm. MRMPBX observations beyond 11.5m upto a depth of 25m showed that there was no movement beyond 11.5m.

MRMPBX observations at RD-80 center of crown for different depths are shown in Fig. 4.2 and the displacement recordings are given in Table 4.2. During initial 27 days, where there was no side slashing done, surface displacement was 3-4mm and this was recorded at 0.7m depth also indicating that the SFRS had just begun to separate from the roof and there was no movement beyond that. Once the side slashing of the crown started at this location, the surface displacement (6-52mm) and displacement at 0.7m depth (5-47mm) increased. Also separation at other deeper horizons was observed with further side slashing. In this case also, joints were found separating beyond the bolted horizon of 8m. MRMPBX recordings indicated that there was no movement beyond 9.5m depth. Monitoring done for 197 days showed displacement of 52mm at surface, 47mm at 0.7m depth, and displacements in the range of 2-31mm at other deeper points. Magnitude of joint separation varied from 1-16mm at various horizons. After installation of the steel ribs in the crown, MRMPBX was extended below the ribs. Further monitoring of MRMPBX did not indicate any increase in displacement in crown.

	Joint separation (mm)							
		4	4	6	3	0	0	0

During initial 8 days there was no displacements at this location. With the starting of the side slashing at this location, surface displacement of 7mm was noted after 17 days and 4mm displacement at 0.7m and 5m depths. Monitoring done for 163 days before the installation of the ribs in the crown recorded 18mm of surface displacement, 10mm at 0.7m depth and 14mm at 5m depth. Displacements were observed upto 9m depth. Joint separation of 3 to 10mm was observed at various depths. MRMPBX recordings did not show any significant movement beyond 9m depth. After installation of the steel ribs in the crown, MRMPBX was extended below the ribs. Further monitoring of MRMPBX did not indicate any increase in the displacement of the crown (Fig. 4.3).

MRMPBX observations at center of crown at RD-150 are shown in Fig. 4.4 and the displacement recordings are given in Table 4.4. Installation of MRMPBX at this location was delayed due to site constraints and by the time the MRMPBX was installed, side slashing at this location was over. This MRMPBX was monitored for 163 days and surface displacement of 7mm was recorded. At 0.7m depth, 2mm displacement was recorded and beyond 0.7m, the displacements were negligible. After installation of the steel ribs in the crown, this MRMPBX could not be extended below the ribs and could not be monitored further (Fig. 4.4).

Fig. 4.4 Displacement at the center of crown of powerhouse cavern at RD-150

Table 4.4 MRMPBX readings at RD-150 center of crown

Elapsed Time (Days)	Anchor Depth (m)								
	Surface	0.7	2.8	4.5	8.5	12.5	16.5	20.5	21.5
	Displacement (mm)								
0	0	0	0	0	0	0	0	0	0
8	-1	-1	0	-1	0	-1	-1	-1	0
17	2	2	2	0	2	-1	1	-1	0
27	3	2	2	1	2	-1	1	-1	0
39	3	1	-1	-1	0	-1	-1	-1	0
135	6	1	-1	-1	0	-1	-1	-1	0
163	7	2	0	-1	1	-1	-1	0	0
	Joint Separation (mm)								
		5	2	1	-2	2	0	-1	0

MRMPBX observations at the center of the crown clearly indicated that, side slashing accounted for 71-88% of total displacement (when central gullet of 7m wide is side slashed on one side, span increased to 13.7m, and side slashing on the other side increased the span to 20.4m). In most cases, 80-100% of total joint separation took place within 10m into the crown. Joint separation within bolted horizon of 8m varied from 68-100% of total separation. Within 0.7m depth, joint separation varied from 9.6-71.4% of total separation. This clearly indicated detachment of SFRS from the roof. Bolt length of 8m was not sufficient when the side slashing of the crown was done. Displacements above the bolted horizon as a result of separation of joint was making the bolting action ineffective when the span was increasing as a result of side slashing.

4.1.2 Movement in the Widened part of Crown

After side slashing of the crown and supporting it with SFRS and rock bolts, four more extensometers were installed in the widened portion of the crown at RD-15DCR (downstream side), RD-15UCR (upstream side), RD-80UCR and RD-130UCR.

MRMPBX (installed after side slashing) observations at RD-15DCR are given in Table 4.5 and values are depicted in Fig. 4.5. In this case, displacement of 12mm was observed at a depth of 22.5m indicating that joint separation was taking place at deeper points as well. As MRMPBX at the center of crown at RD-15 indicated initiation of joint separation with side slashing, observation from this instrument further

corroborated that joint separation was extending to the side of the crown also. Rate of movement in the initial 40 days varied from 0.27-1.0mm per day (evident from steep portion of graph). Rock bolts in this case failed to arrest the movement, as joint separation in the roof had already started with side slashing. This instrument was extended below steel ribs. After supporting with the steel ribs, there was no further displacement (Fig. 4.5).

Fig. 4.5 Displacement at the downstream side of crown of powerhouse cavern at RD-15

MRMPBX (installed after side slashing) observations at RD-15UCR are shown in Fig. 4.6. Displacement recordings are given in Table 4.6. This instrument was monitored for 28 days. Surface displacement of 53mm was recorded. Also, displacement of 10mm was noticed at a depth of 16.5m, which confirmed that joint separation was taking place at deeper horizons.

	Joint Separation (mm)						
		34	-1	10	-9	8	11

MRMPBX (installed after side slashing) observations at RD-80UCR are shown in Fig. 4.7 and displacement recordings are given in Table 4.7. There was no joint movement for initial 27 days after installation of the instrument. After a period of 139 days, there was 97mm of surface displacement. Joint separation was observed upto 6.2m depth into the crown. Joint separation was varying from 1 to 56mm. Recordings at this instrument showed that in some cases, the time period for starting of the separation of the joints is more, and over a period of time, separation starts and moves up in the crown of the powerhouse.

Fig. 4.7 Displacement at the upstream side of crown of powerhouse cavern at RD-80

MRMPBX (installed after side slashing) observations at RD-130UCR are shown in Fig. 4.8 and displacement recordings are given in Table 4.8. In this case also, joint separation was taking place upto a height of 7m into the crown. Surface displacement of 18mm and joint separation upto 9mm was recorded from this instrument.

MRMPBX (installed after side slashing) observations in the widened portion of the crown indicated that joint separation that took place in the central portion of crown, extended to sides also. Joint separation started within 7 days upto 22.5m depth into the crown and accelerated between 29 to 41 days with 42-77% of total displacement. With an increase in span (20.4m), joint separation started at deeper depths in the crown. This caused roof collapses at few places. Fig. 4.9 shows one such collapse where roof came down along with rock bolts, which corroborated MRMPBX data (joint separation at deeper depths into crown).

MRMPBX recordings were used to calculate critical strain as per Sakurai et al. (1997). Strains calculated are plotted on Sakurai's warning level graphs and shown in Fig. 4.10. Uniaxial compressive strength of rock mass was taken as 6.27MPa (Table 3.3). Calculated strains are tabulated in Table 4.9. At most of the places, critical strain was lying between warning level-I and warning level-III. At RD-15, critical strain observed was 1.13% and was approaching warning level-III.

4.1.3 Load on Rock Bolts in the Crown

Vibrating wire anchor load cells were installed on some of the rock bolts in the crown of powerhouse cavern. Load cell observations on rock bolts is shown in Fig. 4.11 and observations are tabulated in Table 4.10.

Fig. 4.11 Axial load on rock bolts in the crown of powerhouse cavern

Load cell on rock bolt at RD-15 center of crown showed maximum load of 18.17t. At that time cracks started appearing in the crown at this location and load on the rock bolts started decreasing (due to loss of tension in the bolt) and lost about 1.33t and recorded load of 16.84t. Load cell could not be monitored further due to installation of the steel ribs. Rate of increase of load varied from 0.01-0.8t/day.

Load cell at RD-80 crown was showing increasing trend and recorded maximum load of 13.57t before it was removed for steel rib placement. Rate of increase of load varied from 0.01-0.14t/day. Load cell at RD-80 upstream side of the crown also showed maximum rate of increase of 0.14t/day and recorded maximum load of 12.02t.

Load cell on rock bolt at RD-110 crown recorded maximum load of 21.01t (70% of yield load) and showed rate of increase in the range of 0.01-0.22t/day. Other load cells at RD-90, RD-100, RD-130 and RD-150 showed loads in the range of 5.20-10t and showed rate of increase in load varying from 0.01t/day to 0.04t/day.

From Fig. 4.11 it could be noted that at RD-15 crown, load on the rock bolt was steadily increasing at a rate varying from 0.01 to 0.8t/day. After 107 days, load cell recorded maximum load of 18.17t. At this point MRMPBX at this location recorded surface displacement of 67mm (Fig. 4.1) and minor cracks started appearing on the surface. This resulted in loss of tension in the rock bolt as indicated by load cell readings. Similar observation was made at RD-80 upstream side, where load cell recorded maximum load of 13.31t after a period of 139 days and MRMPBX recorded displacement of 97mm.

During the monitoring period, load cells could measure load upto 70% of yield load on some of the bolts. Some of the load cells showed increasing trend, but monitoring could not continue as steel ribs with back fill concrete was put in the crown as final support. Wherever cracks appeared in the crown, there was loss of tension in the bolts which was evident in the load cell observations.

4.1.4 Load on the Steel Ribs in the Crown

While installing steel ribs in the crown of powerhouse cavern, load cells were installed on the ribs at EL-533 on both upstream and downstream side. Load cell recordings on upstream and downstream side are given in Tables 4.11 and 4.12 respectively. Axial load on ribs on upstream side and downstream side are shown in Figs. 4.12 and 4.13 respectively.

Fig. 4.12 Axial load on steel ribs on upstream side in the crown of powerhouse cavern

Fig. 4.13 Axial load on steel ribs on downstream side in the crown of powerhouse cavern

Figs. 4.14 and 4.15 show axial load on upstream side and downstream of the steel ribs during benching of powerhouse cavern with time period of each bench (B1-B11) marked on the graphs.

Fig. 4.14 Axial load on steel ribs on upstream side during benching (B1-B11) in the crown of powerhouse cavern

Fig. 4.15 Axial load on steel ribs on downstream side during benching (B1-B11) in the crown of powerhouse cavern

Figs. 4.16 and 4.17 show rate of loading on upstream and downstream side of steel ribs during extraction of each bench.

Fig. 4.16 Rate of loading on steel ribs on upstream side during benching

Fig. 4.17 Rate of loading on steel ribs on downstream side during benching

Summary of change in load on steel ribs during excavation of each bench is given in Table 4.13. Bench wise explanation of loading on steel ribs is described below.

Bench-1 (B-1, EL 531 to 528.5)

During excavation of first bench, maximum load recorded on upstream side was 29t at RD-143.4, with rate of loading of 0.13t/day. Loads at RD-18.5, RD-56.5, RD-76, RD-126 and RD-173.5 on upstream side were 8.67t, 17t, 18t, 15t and 16.4t, respectively. Total load increase at RD-56.5 was 13.88t with a rate of 0.09t/day (Fig. 4.16).

On downstream side, maximum load recorded was 54.78t at RD-173.5, an increase of 38.75t with 0.24t/day. At RD-76, load recorded was 19t (increase of 11.9t) with 0.07t/day (Fig. 4.17). Loads at RD-18.5, RD-56.5, RD-126 and RD-143.4 were 10t, 5t, 12.5t and 14t respectively.

Table 4.13 Summary of change in load in steel ribs during each benching at powerhouse cavern

Upstream Side													
	Change in Load(t) for Excavation of each Bench												
RD/ Bench	1	2	3	4	5	6	7	8	9	10	11	Max	Min

Min	2.9	5	2.54	5	0.2	0	1.5	-4.3	4.76	-0.53	-0.58		

Bench-2 (B-2, EL 528.5 to 525)

Excavation of second bench recorded acceleration in load on upstream side at RD-143.4 and RD-56.5. Maximum load recorded at RD-143.4 was 44t (an increase of 27t) with 0.26t/day. At RD-56.5, maximum load was 45t (an increase of 37.1t) with 0.36t/day. At other locations, rate of loading varied from 0.02 – 0.06t/day (Fig. 4.16).

On downstream side, load at RD-173.5 increased to 72.5t (an increase of 38.5t) with 0.38t/day. At RD-76, load increased to 24.5t (an increase of 11.5t) with 0.11t/day. Loads at RD-18.5, RD-56.5, RD-126 and RD-143.4 were 16t, 7.6t, 16.5t and 19t respectively with loading rates of 0.05-0.10t/day (Fig. 4.17).

Bench-3 (B-3, EL 525 to 521.5)

On upstream side, load at RD-143.4 increased to 45.37t (an increase of 22.07t) with 0.37t/day. Load at RD-56.5 increased to 49.49t (an increase of 35.07t) with 0.58t/day (Fig. 4.16). Load cells at other locations recorded loading rates between 0.04t/day and 0.08t/day.

On downstream side, load at RD-173.5 increased to a maximum of 76t (an increase of 27.20t) with 0.45t/day (Fig. 4.17). At other locations rate of loading varied from 0.04-0.18t/day.

Bench-4 (B-4, EL 521.5 to 518.5)

On upstream side, maximum load at RD-143.4 and RD-56.5 was 44t (an increase of 5.32t with 0.10t/day) and 52t (an increase of 28.42t with 0.55t/day), respectively. There was no change in load at RD-76 and other locations showed loading rates of 0.07-0.10t/day (Fig. 4.16).

On downstream side, load at RD-173.5 increased to 88t (an increase of 21t with 0.40t/day). Load at other locations increased in the range of 5-10.3t with 0.10-0.20t/day (Fig. 4.17).

Bench-5 (B-5, EL 518.5 to 515.5)

On upstream side, maximum load at RD-143.4 and RD-56.5 was 54t (an increase of 10.3t with 0.20t/day) and 64.5t (an increase of 17.9t with 0.35t/day), respectively (Fig. 4.16). Load cells at RD-18.5, RD-126 and RD-173.5 showed an increase of 4.6 to 7.5t with 0.09- 0.15t/day whereas, RD-76 recorded decrease of 1.27t.

On downstream side, load at RD-173.5 increased to 91.36t. However, total increase in load during excavation of this bench was only 8.36t. With the excavation of bus duct No.3 during the excavation of 5th bench, the load on the ribs started decreasing possibly due to the deformations in the bus duct (as the location of bus duct is just beneath it). There was a reduction of 20t (Fig. 4.15). However, towards the end, load started increasing as excavation of passage to the transformer hall and excavation of sixth bench started. Load cells at RD-56.5 and RD-76 recorded increase of 10t (0.2t/day) and 6.6t (0.13t/day).

Bench-6 (B-6, EL 515.5 to 513)

On upstream side, loads at RD-143.5 increased at 0.24t/day to 57.5t. At RD-56.5 load of 69.3t was measured at a rate of 0.22t/day. Total increase in load during excavation of 6th bench was 8.9t and 8.2t at RD-143.4 and RD-56.5 respectively. Loads at other locations showed increase of 1.48t to 4.40t during this period (Fig. 4.14).

On downstream side, load at RD-173.5 increased from 80t to 86t, an increase of 6t. Load at RD-56.5 increased from 18t to 24t at a rate of 0.16t/day. At other locations increase in load varied in the range of 0.5t to 1.5t (with rate of 0.01 to 0.04t/day) (Fig. 4.15 and 4.17)

Bench-7 (B-7, EL 513 to 510)

On upstream side, loads continued to rise at RD-143.4 and RD-56.5 during excavation of 7th bench and recorded load of 60.8t and 70t respectively (an increase of 3.54t (0.05t/day) and 7t (0.11t/day), respectively). During this period at RD-18.5, there was an increase of 2.9t (0.04t/day) (Fig. 4.14 and 4.16).

On downstream side, load at RD-173.5 increased further and recorded a load of 94t, an increase of 10t at 0.15t/day (Fig. 4.15 and 4.17). At other locations, load increased in the range of 1.5t to 5.20t (0.02 to 0.08t/day).

Bench-8 (B-8, 510 to 507)

On upstream side, RD-56.5 recorded load of 82t, an increase of 15t at 0.24t/day. At other locations, loads increased in the range of 0.35t-4.66t at 0.01t/day to 0.08t/day.

On downstream side, load at RD-173.5 increased further and recorded a load of 102.5t, an increase of 7.7t at 0.12t/day (Fig. 4.15 and 4.17). At RD-126, there was an increase of 8t (0.13t/day). At other locations, load increased in the range of 2.9t to 6.99t (0.05 to 0.11t/day).

Bench-9 (B-9, 504 to 507)

On upstream side, RD-56.5 recorded load of 99.45t, an increase of 27.49t at 0.20t/day. At other locations, loads increased in the range of 1.64t-8.00t at 0.01t/day to 0.06t/day (Fig. 4.14 and 4.16).

On downstream side, load at RD-56.5 rose to 55.16t, an increase of 30.16t at 0.22t/day. Similarly at RD-173.5, load increased further and recorded a load of 124.6t, an increase

of 36.75t at 0.27t/day (Fig. 4.15 and 4.17). At RD-126, there was an increase of 10.26t (0.08t/day). At other locations, load increased in the range of 4.26t to 7.45t (0.03 to 0.06t/day).

Bench-10 (B-10, 501 to 504)

On upstream side, RD-56.5 recorded load of 99.45t, an increase of 24.42t at 0.17t/day. At other locations, loads increased in the range of 1.01t-6.11t at 0.01t/day to 0.04t/day (Fig. 4.14 and 4.16).

On downstream side, load at RD-56.5 rose to 55.16t, an increase of 29.16t at 0.20t/day. Similarly at RD-173.5, load increased further and recorded a load of 125t, an increase of 31.91t at 0.22t/day (Fig. 4.15 and 4.17). At RD-126, there was an increase of 7.39t (0.05t/day). At other locations, load increased in the range of 5.48t to 7.39t (0.04 to 0.05t/day).

Bench-11 (B-11, 499.5 to 501)

On upstream side, RD-56.5 recorded load of 104t, an increase of 23.76t at 0.18t/day (Fig. 4.14 and 4.16). At other locations, loads increased in the range of 5.02t-6.07t at 0.04t/day to 0.05t/day.

On downstream side, load at RD-56.5 rose to 58t, an increase of 28.84t at 0.22t/day. Similarly at RD-173.5, load increased further and recorded a load of 127t, an increase of 25.90t at 0.19t/day (Fig. 4.15 and 4.17). At RD-126, there was an increase of 8.90t (0.07t/day).

Excavation of bench-3 had maximum rate of increase of load on the steel ribs in both upstream and downstream sides of crown with maximum rate of 0.56t/day and 0.45t/day, respectively. On upstream side, excavation of benches 2, 3, 4 and 5 had maximum influence on load in steel ribs at RD-56.5 and RD-143.4 with more than 0.25t/day. This influence zone comes within 1.05 times the width of the cavern. Beyond that height (i.e. excavation of 6th bench onwards, the rate of loading is less than 0.25t/day). On downstream side, excavation of bench-1 to bench-5 had maximum influence on load in steel ribs at RD-173.5 with more than 0.25t/day. In this case also, this influence zone comes within 1.05 times the width of the cavern.

Although, there was an average increase of 24.74t each at RD-56.5 upstream, during excavation of bench-9, 10 and 11, rate of loading was less as time for each benching was 136.5 days compared to average benching period of 54.83 days for benches 3 to 8. Similar behaviour was observed at RD-56.5 downstream and RD-173.5 downstream.

4.1.5 Movement in the Side Walls

Instrumentation in the walls of cavern continued with excavation of benches. Reflective targets were installed at elevations 525, 520, 515 and 506 on both walls at RD-15, RD-65, RD-110m and RD-150m. Cumulative convergence of main walls of cavern was measured using total station. Cumulative convergence observations at EL-525 are shown in Fig. 4.18 and data is listed in Table 4.14.

Fig. 4.18 Cumulative convergence of walls at powerhouse cavern at EL-525

At EL-525, cumulative convergence at RD-65 and RD-110 was almost similar (305mm) during the excavation of the cavern and followed same trend (Fig. 4.18). However, during post excavation period, convergence at RD-65 was higher (355.2mm) than convergence at RD-110 (328.8mm).

Cumulative convergence observations at EL-520 are shown in Fig. 4.19 and data is listed in Table. 4.15.

Fig. 4.19 Cumulative convergence of walls at powerhouse cavern at EL-520

At EL-520, maximum convergence was recorded at RD-110 (321.4mm) and RD-65 (218.8mm) recorded lower convergence than RD-150 (256.9mm) as shown in Fig. 4.19. Convergence at RD-15 (located at service bay area) at EL-525 (135.3mm) and EL-520 (133.3mm) showed a different trend of convergence at other points in the unit bay area.

Cumulative convergence observations at EL-515 are shown in Fig. 4.20 and data is listed in Table 4.16.

Fig. 4.20 Cumulative convergence of walls at powerhouse cavern at EL-515

At EL-515, maximum convergence was recorded at RD-110 (314.56mm), followed by RD-150 (290.78mm) and RD-65 (199.59mm) as shown in Fig. 4.20.

Fig. 4.22 Cumulative convergence of walls at powerhouse cavern at EL-525 during excavation of main benches

Fig. 4.23 Cumulative convergence of walls at powerhouse cavern at EL-520 during excavation of main benches

Fig. 4.24 Cumulative convergence of walls at powerhouse cavern at EL-515 during excavation of main benches

Convergence rates calculated from the measured convergence are presented in Figs. 4.25 to 4.28.

Fig. 4.25 Convergence rate of walls at powerhouse cavern at EL-525

Fig. 4.26 Convergence rate of walls at powerhouse cavern at EL-520

Fig. 4.27 Convergence rate of walls at powerhouse cavern at EL-515

Fig. 4.28 Convergence rate of walls at powerhouse cavern at EL-506

Convergence rate during the excavation of main benches at EL-525 was very high (maximum at RD-65, 4.49mm/day and at RD-150, 2.6mm/day) as shown in Fig. 4.25, which reduced to 0.5mm/day at the end of complete excavation. At EL-520, convergence rate upto 1.95mm/day was observed as shown in Fig. 4.26 and reduced to 0.5mm/day at the end of complete excavation. At EL-515, convergence rate upto 2.08mm/day was observed as shown in Fig. 4.27. This reduced to 0.66mm/day at the end of complete excavation. At EL-506, convergence rate upto 2.47mm/day was observed as shown in Fig. 4.28 and reduced to 0.52mm/day at the end of complete excavation. Total convergence measured during a period of 4.5 years and the computed strain (taking the width of powerhouse cavern as 20.4m) are summarised in Table 4.19.

Table 4.19 Summary of convergence observations at powerhouse cavern

	EL-525		EL-520		EL-515		EL-506

*could not monitor it during post excavation period and excavation was done upto EL-515m only (service bay area)

Convergence percentage and rate of change in convergence were calculated during excavation of main benches, during entire period of excavation and during post excavation period from the original data and are presented in Table 4.20.

In the service bay area (RD-15), where excavation was done upto EL-514.5m, convergence observed at EL-525 and EL-520 were 135.3mm and 133.3mm, respectively. Percentage strain calculated during the monitoring period taking width of the powerhouse cavern (20.4m) was 0.66%. Whereas in unit bay area (RD-60 to RD-206) where excavation extended till EL-499, convergence upto 355.2mm was observed with percentage strain of 1.74%. At EL-520, maximum percentage strain was 1.58% at RD-110 and at EL-515, maximum percentage strain was 1.54% at RD-110. At EL-506, the maximum percentage strain observed was 0.92% at RD-150.

RD-110	154.56	-	-	138.12 (89.36%)	0.50	16.44	0.030
RD-150	188.20	-	-	165.32 (87.24%)	0.59	22.88	0.040

It was observed that 49-58% of total measured convergence during a period of 4.5 years occurred during the excavation of main benches, which reached to 87-89% when all excavation activity was completed in the powerhouse complex. This indicates that about 11%-13% of total observed convergence occurred during post excavation period.

Average convergence rate during excavation of benches varied from 0.56mm/day to 0.67mm/day, whereas, convergence rates during other miscellaneous excavations varied from 0.38 to 0.49mm/day. However, for entire excavation period, the average convergence rate varied from 0.25mm/day to 0.65mm/day. During the post excavation period (monitored for 3 years), convergence of 16-50mm was observed at various locations (Table 4.20). Average convergence rate during the post excavation stage varied from 0.021mm/day to 0.063mm/day.

Monitoring of cumulative convergence between upstream and downstream walls of powerhouse cavern indicated high displacement of side walls with strain varying from 0.92 to 1.74% in the unit bay area and upto 0.66% in the service bay area. Convergence data clearly indicated that in the cavern in Himalayas, where rock mass predominantly consisted of phyllites and phyllitic quartzites, rock mass continue to deform even after the completion of excavation.

4.1.6 Load on Rock Bolts in the Walls

Rock bolts (12m long Dywidag make) in upstream and downstream walls of powerhouse cavern were monitored with vibrating wire anchor load cells. Build-up of load in the rock bolt was monitored by regular recording with continuation of excavation of lower benches. Monitoring of these load cells continued during post excavation stage also. Behaviour of rock bolts at EL-529, EL-525, EL-520, EL-515 and EL-506 on upstream and downstream walls are discussed in this section. Entire load cell data in the walls of powerhouse cavern is given in Appendix-2.

EL-529: Load cell data at EL-529 (RD-123 u/s and RD-123 d/s) is shown in Fig. 4.29 and period of benching is marked in the plot and is shown in Fig. 4.30.

Fig. 4.29 Axial load on rock bolts at EL-529 on walls of powerhouse cavern

At RD-123 upstream, rock bolt was pre-tensioned to 30.59t. Load on the rock bolt started decreasing at a steady rate. For initial 67 days, there was a reduction in load of 3.57t. Subsequently, the load further decreased at faster rate and there was a further reduction of 4.43t during a period of another 30 days. Thus after a period of 116 days, the load on the rock bolt was 22.46t (a decrease of 8.13t). During this period, the excavation of second bench had already begun. Since, the pre-tensioning of the rock bolts was very high, the rock mass near the wall surface might have lost the capacity to transfer the load arising out of the excavation of the lower bench to rock bolt and allowing the wall deformation to take place. However, when the excavation of the 3rd bench started, the load on the rock bolts stabilized and there was marginal increase in the load on rock bolt. The load loss of 8t occurred during the excavation of 1st bench and 4t during the excavation of 2nd bench. There was an increase in load of 1.22t due to the excavation of the 3rd bench. The load increased by only 0.39t during the excavation of 4th bench.

Fig. 4.30 Axial load on rock bolts at EL-529 on walls of powerhouse cavern during excavation of main benches

Load cell at RD-123 downstream side was pre-tensioned to 19.37t. It could be noted from Fig. 4.30 that there was a reduction of 2.45t during the initial 10 days. Later, the load on rock bolt started increasing. Load on rock bolt increased by 4.26t during a period of 23 days. There was an increase of 18.16t (increase from 16.93t to 35.09t) due to the excavation of 2nd bench. There was an increase of 7.36t (from 28.54t to 35.90t) load on the bolt due to the excavation of 3rd bench. The increase in load during the excavation of the 4th bench was 6.13t, which also suggested the diminishing influence of the lower benches on the rock bolt.

EL-525: Load cell data of rock bolts at EL-525 upstream wall and data during excavation of main benches are shown in Figs. 4.31 and 4.32, respectively. Load cells at RD-16.8, RD-62 and RD-106 on upstream wall at EL-525m were installed during the excavation of bench-3. Load on rock bolts at RD-16.8 and RD-62 started increasing when bench-4 excavation started. At RD-16.8, maximum increase in load was recorded during excavation of bench-4 (9.71t). At RD-62, maximum increase in load occurred during excavation of bench-5 (18.60t). At RD-106, excavation of benches had very

little effect. Rock bolt at RD-62 failed and load of 43.01t was recorded by load cell before failure.

Fig. 4.31 Axial load on rock bolts at EL-525 on upstream wall of powerhouse cavern

Fig. 4.32 Axial load on rock bolts at EL-525 on upstream wall of powerhouse cavern during excavation of main benches

Load cell data on rock bolts at EL-525 downstream wall and data during excavation of main benches are shown in Figs. 4.33 and 4.34, respectively.

Fig. 4.33 Axial load on rock bolts at EL-525 on downstream wall of powerhouse cavern

Fig. 4.34 Axial load on rock bolts at EL-525 on downstream wall of powerhouse cavern during excavation of main benches

Load cells at RD-15, RD-16, RD-69 and RD-110 on downstream wall at EL-525 were installed during excavation of bench-3 and 4. Excavation of bench-5 had maximum influence on the rock bolts at RD-15, RD-16 and RD-69, with an increase of 7.5t, 9.83t and 14.06t, respectively. Excavation of bench-4 had increased load at RD-110 by 3.57t.

EL-520: Load cell data of rock bolts at EL-520 upstream wall and data during excavation of main benches are shown in Figs. 4.35 and 4.36, respectively.

Load cells at RD-15, RD-65, RD-110 and RD-150 on upstream wall at EL-520 were installed during the excavation of bench-4. Excavation of bench-5 had maximum influence on rock bolts at RD-15, RD-65, RD-110 and RD-150 with an increase of 9.61t, 13.24t, 5.18t and 11t, respectively.

Fig. 4.35 Axial load on rock bolts at EL-520 on upstream wall of powerhouse cavern

Fig. 4.36 Axial load on rock bolts at EL-520 on upstream wall of powerhouse cavern during excavation of main benches

Load cell data on rock bolts at EL-520 downstream wall and data during excavation of main benches are shown in Figs. 4.37 and 4.38, respectively.

Fig. 4.37 Axial load on rock bolts at EL-520 on downstream wall of powerhouse cavern

Fig. 4.38 Axial load on rock bolts at EL-520 on downstream wall of powerhouse cavern during excavation of main benches

On downstream wall, load cells at RD-15, RD-65, RD-110 and RD-150 were installed during excavation of bench-4. Excavation of bench-5 had maximum influence on rock bolts at RD-15, RD-65 and RD-150 with an increase of 12.98t, 9.49t, and 7.48t, respectively. At RD-110, bench-6 had maximum influence with an increase of 9.60t.

EL-515: Load cell data of rock bolts at EL-515 upstream wall and data during excavation of main benches are shown in Figs. 4.39 and 4.40, respectively.

Load cells at RD-65, RD-110 and RD-150 on upstream wall at EL-515 were installed during the excavation of bench-6 and 7, whereas load cells at RD-120 and RD-142 were installed later during excavation of benches 9, 10 and 11. Excavation of bench-7 had maximum influence on rock bolts at RD-110 and RD-150 with an increase of 1.28t and 7.1t, respectively. Load at RD-65 increased continuously during the excavations of bench-8 to bench-11 in the range of 2.98t to 8.66t.

Fig. 4.39 Axial load on rock bolts at EL-515 on upstream wall of powerhouse cavern

Fig. 4.40 Axial load on rock bolts at EL-515 on upstream wall of powerhouse cavern during excavation of main benches

Load cell data on rock bolts at EL-515 downstream wall and data during excavation of main benches are shown in Figs. 4.41 and 4.42, respectively.

Fig. 4.41 Axial load on rock bolts at EL-515 on downstream wall of powerhouse cavern

Fig. 4.42 Axial load on rock bolts at EL-515 on downstream wall of powerhouse cavern during excavation of main benches

On downstream wall, load cells at RD-65, RD-110 and RD-150 were installed during excavation of bench-6 and 7. Excavation of bench-7 had maximum influence on rock bolts at RD-110 and RD-150 with an increase of 12.57t and 3.67t, respectively. Load at RD-65 increased continuously during the excavations of bench-8 to bench-11 in the range of 0.33t to 4.03t.

EL-506: Load cell data of rock bolts at EL-506 upstream wall and data during excavation of main benches are shown in Figs. 4.43 and 4.44, respectively.

Fig. 4.43 Axial load on rock bolts at EL-506 on upstream wall of powerhouse cavern

Load cells at RD-65, RD-110 and RD-150 on upstream wall at EL-506 were installed during the excavation of bench-8 and 9. Excavation of bench-8 had maximum influence on rock bolt at RD-150 with an increase of 13.03t. Load at RD-110 increased continuously during the excavations of bench-9 to bench-11 in the range of 8.74t to 16.24t.

Fig. 4.44 Axial load on rock bolts at EL-506 on upstream wall of powerhouse cavern during excavation of main benches

Load cell data on rock bolts at EL-506 downstream wall and data during excavation of main benches are shown in Figs. 4.45 and 4.46, respectively.

Fig. 4.45 Axial load on rock bolts at EL-506 on downstream wall of powerhouse cavern

Fig. 4.46 Axial load on rock bolts at EL-506 on downstream wall of powerhouse cavern during excavation of main benches

On downstream wall, load cells at RD-65, RD-110 and RD-150 were installed during excavation of benches 8 to 10. Excavation of bench-8 had maximum influence on rock bolts at RD-150 with an increase of 3.84t, whereas, load at RD-110 increased continuously during the excavation of benches 9 to 11 in the range of 1.44t to 1.86t.

Load on 12m Dywidag rock bolts on the walls of powerhouse cavern is summarised in Table 4.21. Percentage of increase in load after benching, after complete excavation and post excavation stage were calculated with respect to the final load on the rock bolt monitored during post excavation stage. Percentage of >100% indicates that final load on that particular rock bolt at the end of monitoring period is less than the load under reference and negative percentage indicates that load under reference is less than the load in the previous stage.

Table 4.21 Summary of load on rock bolts on the walls of powerhouse cavern

	After Benching		After Complete Excavation		Post Excavation

On downstream wall at EL-525, about 73 to 95.5% of final load on the bolt (at the end of monitoring period) was recorded during the excavation of main benches and 3.1 to 11.8% was observed during excavation of other tunnels, and 1.4 to 15.2% was observed during post excavation period. At EL-520, about 49.4 to 66.1% of final measured load on the rock bolt was recorded during the excavation of main benches, 11 to 19.1% was observed during other excavations, and 22.9 to 31.4% was observed during post excavation period. At EL-515, about 45 to 52.1% of final measured load on the rock bolt was recorded during the excavation of main benches and -4.2 to 44.4% was observed during other excavations and 4.2 to 59.2% was observed during post excavation period. At EL-506, about 37.5 to 68.1% of final measured load on the rock bolt was recorded during the excavation of main benches and -12 to 41.3% was observed during other excavations, and 21.2 to 43.9% was observed during post excavation period. The data indicated that rock bolts at higher elevations have experienced higher percentage of final recorded load during excavation of main benches and bolts at lower elevations experienced higher percentage of final load during post excavation period.

On upstream wall at EL-525, rock bolt at RD-62 failed before complete excavation and maximum load recorded was 43.01t, out of which 40.54t was recorded during excavation of main benches. At EL-520, about 72 to 119.8% of final measured load on the rock bolt was recorded during the excavation of main benches, -4.1 to 8.7% was

observed during other excavations and -28.5 to 31% was observed during post excavation period. Data shows reduction in load on bolts after bench excavation and during post excavation period. At EL-515, about 39.6 to 199.7% of final measured load on the rock bolt was recorded during the excavation of main benches, -7.5 to 140.7% was observed during other excavations, and -240.4 to 45.8% was observed during post excavation period. At EL-506 also, about 92.2 to 102.6% of final measured load on the rock bolt was recorded during the excavation of main benches, -1.2 to 26.5% was observed during other excavations, and -18.7 to 1.1% was observed during post excavation period. It could be noted that on upstream wall, bolts at almost all elevations have experienced higher percentage of final recorded load during the excavation of benches and reduction of load in some cases after complete excavation and during post excavation period.

Bolts on the upstream wall experienced loads of higher magnitude compared to the bolts on downstream wall. During benching, bolts on upstream wall at almost all elevations were loaded higher (average 87.7%), whereas on downstream wall, only bolts at higher elevation (EL-525, average 85.3%) experienced higher loads. During post excavation, load on the bolts on downstream wall was greater (average 21.4%) than the load on bolts on upstream wall (average 8.7%). In many cases there was reduction in load on upstream wall.

4.1.7 Instrumented Bolt Observations

Instrumented bolts were installed at EL-506 on both upstream and downstream walls of powerhouse cavern at RD-65, RD-110 and RD-150. At RD-140, RD-150 bolts were also installed on upstream wall at EL-515. Strain measured along the rock bolt at 1m interval was analysed and presented here. Listing of all instrumented bolt observations is given in Appendix-2.

RD-65, EL-506 Downstream Wall: Change in microstrains in instrumented bolt on downstream wall at RD-65, EL-506 are shown in Fig. 4.47.

Fig. 4.47 Change in micro strain in instrumented bolt at RD 65, EL 506 at downstream wall of powerhouse cavern

At RD-65 downstream at EL-506, there was an increase in strain (maximum 1916 microstrain) at 1m depth. At 9m, 10m and 11m depths, there was decrease of strain (-5 to -17 microstrain) and at other depths, there was an increase in strain in the range of 100 to 176 microstrain (Fig. 4.47).

RD-110, EL-506 Downstream Wall: Instrumented bolt observations on downstream wall at RD-110, EL-506 are shown in Fig. 4.48.

At RD 110 downstream, increase in strains were observed at 1m, 2m, 4m and 5m depths with increase of 206.5 and 278 microstrain at 1m and 2m depths (Fig. 4.48).

Fig. 4.48 Change in micro strain in instrumented bolt at RD 110, EL 506 at downstream wall of powerhouse cavern

RD-150, EL-506 Downstream Wall: Instrumented bolt observation on downstream wall at RD-150, EL-506 are shown in Fig. 4.49. At this location, increase in strain was observed at 1m and 2m depth with increase of 7.4 and 6.61 microstrain. There was decrease of strain at all other depths (Fig.4.49).

Fig. 4.49 Change in micro strain in instrumented bolt at RD 150, EL 506 at downstream wall of powerhouse cavern

RD-65, EL-506 Upstream Wall: Recordings made on upstream wall at RD-65, EL-506 are shown in Fig. 4.50. At this location, increase in strain was observed at 1m and 8m depth with an increase of 232.55 and 536.25 microstrain. At other depths, there was decrease in strain in the range of -18.34 to -105.48 microstrain (Fig. 4.50).

Fig. 4.50 Change in micro strain in instrumented bolt at RD 65, EL 506 at upstream wall of powerhouse cavern

RD-110, EL-506 Upstream Wall: Instrumented bolt observations on upstream wall at RD-110, EL-506 are shown in Fig. 4.51.

Fig. 4.51 Change in micro strain in instrumented bolt at RD 110, EL 506 at upstream wall of powerhouse cavern

At RD-110 upstream, increase in strain was observed at 1m to 4m depths with an increase in the range of 216.19 to 1119.63 microstrain. At other depths, there was decrease in strain in the range of -7.43 to -180.63 microstrain (Fig. 4.51).

RD-150, EL-506 Upstream Wall: Results of monitoring of instrumented bolts on upstream wall at RD-150, EL-506 are shown in Fig. 4.52. At RD-150 upstream, increase in strain was observed at 1m depth with an increase of 7.70 microstrain and at all other depths, there was decrease in the strain in the range of -70.35 to -342.82 microstrain (Fig. 4.52).

Fig. 4.52 Change in micro strain in instrumented bolt at RD 150, EL 506 at upstream wall of powerhouse cavern

RD-140, EL-515 Upstream Wall: Instrumented bolt observations on upstream wall at RD-140, EL-515 are shown in Fig. 4.53. At RD-140 upstream at EL-515, increase in strain was observed at 1m depth with an increase of 23.96 microstrain. At other depths, there was decrease in strain in the range of -3.59 to -147.86 microstrain (Fig. 4.53).

Fig. 4.53 Change in micro strain in instrumented bolt at RD 140, EL 515 at upstream wall of powerhouse cavern

RD-150, EL-515 Upstream Wall: Recordings made on upstream wall at RD-150, EL-515 are shown in Fig. 4.54. At RD-150 upstream at EL-515, increase in strain was observed at 1m, 3m and 5m depths with an increase in the range of 7.3 to 63.51 microstrain. At other depths, there was decrease in strain in the range of -3.59 to -147.86 microstrain (Fig. 4.54).

Fig. 4.54 Change in micro strain in instrumented bolt at RD 150, EL 515 at upstream wall of powerhouse cavern

Final change in strain values measured in post excavation stage at various depths in instrumented bolts are summarised in Table 4.22.

Table 4.22 Summary of strain changes in instrumented rock bolts

Depth (m)	Microstrain							
	Upstream Wall					Downstream Wall		
	RD-65 EL-506	RD-110 EL-506	RD-150 EL-506	RD-140 EL-515	RD-150 EL-515	RD-65 EL-506	RD-110 EL-506	RD-150 EL-506
1m	232.55	216.19	7.70	23.96	63.52	1640.91	206.56	7.40
2m	-18.34	449.27	-70.35		-2.37	-121.13	278.24	6.61
3m	-105.48	1119.63	-26.72	-5.13	17.50	-94.32	-26.96	-77.27
4m	-35.87	981.98		-76.74	-84.84	-21.61	453.22	-123.85
5m	-32.50	-180.63	-234.21	-15.77	7.41	-51.49	71.53	-159.42
6m	-88.58	-103.77	-129.60	-64.61	-24.54	-440.45	-199.52	-202.25
7m	-78.44	-127.32	-342.83	-73.15	7.30	51.45	-112.86	-116.02
8m	536.25	-88.19	-205.22	-3.59	-315.60	-101.14	-105.92	-15.15
9m		-156.61	-270.74	-49.33	-93.17	-124.24	-134.60	-20.56
10m		391.43		-70.07	-135.66	-98.22	8.99	-5.98
11m		-17.11	-153.80	-8.67	-401.07	-54.38	-116.30	
12m		-7.43	-38.36	-147.86	-2.43	-8.40	-183.18	-78.53

Strains in the rock bolt measured with instrumented bolt showed that there was an increase in strain at 1m depth in all cases. In some cases, there was an increase in strain upto 4 to 5m depths. At 11m and 12m depths, there was decrease in strain in all cases. Strains measured with instrumented bolts are in agreement with experimental results of Freeman (1978) on fully bonded rock bolts, where it was proved that bolt part closer to the excavation is responsible for picking up the load from rock mass (hence increase in strain) and balance part acts as anchor length, which firmly anchors the bolt to the rock mass (hence decrease in strain).

4.1.8 Pore Water Pressure Observations at Powerhouse Cavern

Piezometers were installed at EL-533, EL-525 and EL-511 in powerhouse cavern. At EL-533, the piezometers were installed at 10m depth. At EL-525, one piezometer was installed at 5m depth and one more piezometer was installed at 10m depth. During operational period, nine more piezometers were installed at EL-504 and EL-500 on powerhouse upstream wall at a depth of 3m, around pressure shaft manifold area. None of the piezometers above EL-500 recorded building up of pore water pressure in the

surrounding rock mass of the powerhouse. Maximum pore water pressure recorded above EL-500 was 0.69kg/cm^2 . It could be noted that at EL-500 there was an indication of water pressure between RD-87 and RD-167 with pore pressure in the range of 0.12 to 1.07kg/cm^2 .

4.2 TRANSFORMER HALL CAVERN

4.2.1 Load on the Steel Ribs in the Crown

While installing steel ribs in the crown of transformer hall cavern, load cells were installed on the ribs at EL-533.6 on both upstream and downstream side. Axial load on ribs on upstream side and downstream side are shown in Figs. 4.55 and 4.56, respectively. All the load cell data in the steel ribs in transformer hall cavern is given in Appendix-3.

Fig. 4.55 Axial load on steel ribs on upstream side in the crown of transformer hall cavern

On upstream side, axial load on the steel ribs increased in the range of 3.4 - 52.67t during the benching and at locations, RD-84.5 and RD-129.4 there was a decrease in the load (3.19 to 9.34t). During post excavation period, load on ribs increased by 0.48 - 54.66t . At RD-70.6, load of 83.06t was measured during post excavation period.

Fig. 4.56 Axial load on steel ribs on downstream side in the crown of transformer hall cavern

On downstream wall, the increase in load during the excavation of benches in transformer hall varied from 14.71t to 48.9t. During post excavation period, the load on the ribs increased in the range of 8.14-14.39t. Maximum load of 64.39t was measured at RD-154.4 on downstream side (Fig 4.56). A summary of load changes in the ribs on upstream and downstream of transformer hall is given in Table 4.23.

Table 4.23 Details of load changes in ribs in the crown of transformer hall

Details of Load on Ribs at Transformer Hall Cavern						
Upstream Side						
RD	Load Changes during Excavation of Benches (t)			Load Changes Post Excavation Period (t)		
	Load at Start of Bench Excavation (t)	Load at End of Bench Excavation (t)	Change in Load (t)	Start Load (t)	End Load (t)	Change in Load (t)
14	10.71	27.94	17.23	-	-	-
70.6	28.33	81	52.67	81	83.06	2.06
84.5	14.45	11.26	-3.19	12.56	35.97	23.41
113.2	1.68	5.08	3.4	6.69	25.8	19.11
129.4	21.9	12.56	-9.34	12.2	12.68	0.48
154.4	20.72	37	16.28	40	47.76	7.76

Details of Load on Ribs at Transformer Hall Cavern						
Downstream Side						
Load Changes during Excavation of Benches (t)				Load Changes Post Excavation Period (t)		
RD	Load at Start of Bench Excavation (t)	Load at End of Bench Excavation (t)	Change in Load (t)	Start Load (t)	End Load (t)	Change in Load (t)
14	3.57	39.11	35.54	35	43.14	8.14
70.6	30.34	54.26	23.92	-	-	0
84.5	0	48.9	48.9	-	-	0
113.2	1.43	16.14	14.71	17.78	28.65	10.87
129.4	9.42	35.4	25.98	-	-	0
154.4	20.55	45	24.45	50	64.39	14.39

Analysis of load cell data on the steel ribs on upstream side of transformer hall, indicated change in load from -9.34 to 52.67t during benching. Decrease in load was observed in the central portion of cavern (RD-84.5 to RD-129.4). During post excavation period, there was an increase in load at all locations (0.48 - 23.41t). On downstream side, there was an increase in load on steel ribs at all locations during benching (14.71-48.9t). During post excavation period, the increase in load was 8.14 - 14.39t. In the later part of post excavation period, load on the steel ribs showed a stable trend (Figs. 4.55 and 4.56).

4.2.2 Load on Rock Bolts in the Walls

Rock bolts (8m long Dywidag make) in upstream and downstream walls of transformer hall cavern were monitored with vibrating wire anchor load cells. Build-up of load in the rock bolts was monitored by regular readings with continuation of excavation of lower benches. Behaviour of rock bolts at EL-532, EL-525 and EL-520, on upstream and downstream walls during excavation and post excavation period are discussed in this section. All the load cell data on rock bolts in transformer hall cavern is given in Appendix-3.

EL-532: Axial load on rock bolts at EL-532 on the walls of transformer hall is shown in Fig. 4.57. During the excavation of benches in transformer hall, load on rock bolts at EL-532 varied from -1.43t to 11.82t. More changes in load were observed on the upstream wall. Maximum load (38.92t) was measured at RD-80 upstream. Post excavation period saw load changes in rock bolt in the range of -3.1t to 6.54t.

Fig. 4.57 Axial load on rock bolts at EL-532 on upstream and downstream wall of powerhouse cavern

EL-525: Axial load on rock bolts at EL-525 on the walls of transformer hall is shown in Fig. 4.58. Load changes on rock bolts at EL-525 was in the range of -5.37t to 10.71t. Maximum load (25.89t) was measured at RD-14 upstream. During post excavation load changes varied from -3.83t to 4.57t. During post excavation period, load cell at RD-60 upstream recorded maximum load of 25.92t (Fig. 4.58).

Fig. 4.58 Axial load on rock bolts at EL-525 on upstream and downstream wall of powerhouse cavern

EL-520: Axial load on rock bolts at EL-520 on the walls of transformer hall is shown in Fig. 4.59. At EL-520, change in load on rock bolts varied from -8.47t to 19.86t and maximum loads were measured at RD-58 u/s (27.84t) and at RD-162 u/s (27.54t). Here also maximum loads were recorded on upstream wall. During post excavation period, the change in load on rock bolts varied from -1.46t to 2.89t.

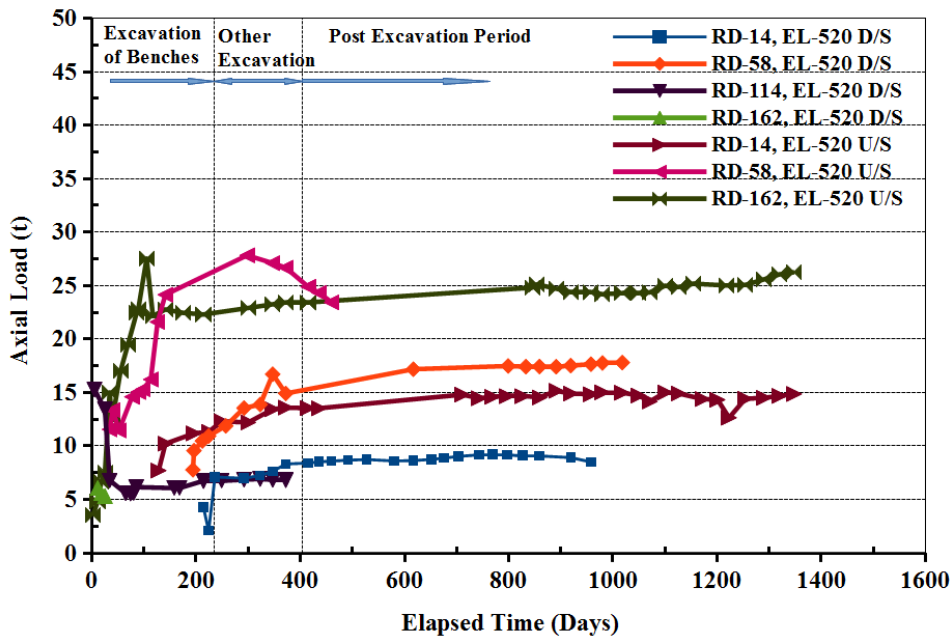

Fig. 4.59 Axial load on rock bolts at EL-520 on upstream and downstream wall of powerhouse cavern

Details of changes in load on rock bolt during excavation and post excavation period are listed in Table 4.24.

Table 4.24 Details of load changes in rock bolts in the walls of transformer hall

Location	After complete Excavation		Post Excavation Period		Final Load on Rock Bolt (t)
	Load (t)	% of Final Recorded Load (t)	Load (t)	% of Final Recorded Load (t)	
EL-532					
RD-80 D/S	15.94	79%	20.1	21%	20.1
RD-81 D/S	6.35	49%	12.89	51%	12.89

RD-60 U/S	20	86%	23.22	14%	23.22
RD-121 U/S	3.69				
EL-520					
RD-14 D/S	8.41	99%	8.51	1%	8.51
RD-58 D/S	15.02	84%	17.81	16%	17.81
RD-114 D/S	6.81	-	-	-	-
RD-162 D/S	5.36	-	-	-	-
RD-14 U/S	13.55	91%	14.87	9%	14.87
RD-58 U/S	24.9	106%	23.44	-6%	23.26
RD-162 U/S	23.41	89%	26.26	11%	26.26

Analysis of load cell data on rock bolts on walls of transformer hall cavern indicated development of load upto 38.92t during excavation period. Most of the rock bolts recorded an increase in load (49 to 196% of final load recorded during post excavation stage) during the excavation period and reduction in load during post excavation period. There was an increase of 21- 51% at EL-532 in three cases and 37% in one case at EL-525 at other locations increase was upto 16% and in five cases, there was reduction

in load during post excavation period. During post excavation period, in general stable trend was observed.

4.2.3 Movements in the Side Walls

Cumulative convergence of main walls of transformer hall cavern was monitored with reflective targets using total station. Convergence observations are depicted in the graphs and excavation periods are marked on the graphs. Listing of all cumulative convergence data in transformer hall cavern is given in Appendix-3. Convergence observation at EL-531 is shown in Fig. 4.60.

Fig. 4.60 Cumulative convergence of walls at transformer hall cavern at EL-531

At EL-531 RD-60, out of total cumulative convergence of 163.31mm, 86.92mm (53.22%) was measured during excavation of benches.

Convergence observation at EL-525 is shown in Fig. 4.61. At EL-525, cumulative convergence in the range of 32.91 to 102.91mm was measured. About 56.51% to 79.38% of total convergence was measured during the excavation of benches.

Convergence observation at EL-520 is shown in Fig. 4.62. At EL-520, cumulative convergence in the range of 19 - 82mm was measured. About 56.51% to 79.38% of total convergence was measured during the excavation of benches.

Fig. 4.61 Cumulative convergence of walls at transformer hall cavern at EL-525

Fig. 4.62 Cumulative convergence of walls at transformer hall cavern at EL-520

Summary of convergence and the computed strain (taking the width of transformer hall cavern as 16m) is summarised in Table 4.25.

Table 4.25 Details of convergence measurements at transformer hall cavern

	Convergence during Excavation of Main Benches (mm)	Convergence after Complete Excavation (mm)	Convergence during Post Excavation Period (mm)	Total Cumulative Convergence (mm)	Per cent Strain
EL-531					
RD-60	86.92 (53.22%)	41.08 (25.15%)	35.31 (21.62%)	163.31	1.02
EL-525					
RD-14	-	19.67 (59.77%)	13.24 (40.23%)	32.91	0.21
RD-60	-	56.5 (65.67%)	29.53 (34.33%)	86.03	0.54
RD-114	47.86 (56.51%)	28.34 (27.54%)	26.71 (25.95%)	102.91	0.64
RD-155	76.69 (79.38%)	11.87 (12.28%)	8.13 (8.41%)	96.69	0.60
EL-520					
RD-14	-	6.47 (33.44%)	12.88 (66.56%)	19.35	0.12
RD-60	-	22.1	33.62	55.72	0.35
RD-121	8.24 (9.13%)	68.5 (75.9%)	13.51 (14.97%)	82.01	0.56
RD-155	12.7 (24.41%)	29.51 (56.72%)	9.82 (18.87%)	39.33	0.33

Percentage strain measured in the walls of transformer hall varied between 0.12 - 1.02%. Convergence rates of all the measurements are shown in Fig. 4.63. Convergence rates during the excavation of benches varied from 0.01 to 0.96mm/day. While excavating other tunnels, convergence rates varied from 0.01 to 0.63mm/day and during post excavation it varied from 0.01 to 0.40mm/day (Fig. 4.63).

Monitoring of cumulative convergence between upstream and downstream walls of transformer hall cavern indicated high displacement of side walls. Maximum convergence recorded at EL-531, EL-525 and EL-520 was 163.31mm, 102.9mm and 82.01mm, respectively. With width to height ratio of 0.65, transformer hall recorded

maximum strain of 1.02%. Considerable amount of convergence was recorded during post excavation period (35.31mm).

Fig. 4.63 Convergence rate of walls at transformer hall cavern

4.3 CROSS TUNNELS IN POWERHOUSE COMPLEX

The behaviour of the cross tunnels was assessed using load cell observations on rock bolts and ribs. Listing of all load cell data in the steel ribs and rock bolts in bus ducts and passage tunnel is given in Appendix-4. Load on the steel ribs in bus ducts and passage tunnels are shown in Fig. 4.64.

Fig. 4.64 Axial load on steel ribs in bus ducts and passage tunnels

It may be noted from Fig. 4.64 that, at bus duct No.1, the load on the left side of the ribs after the backfill was 10.51t. The load started increasing at a faster rate. The rate of loading varied from 0.50t/day to 3.3t/day between 10th day and 60th day from the date of installation and reached 94.28t during 72 days.

Considering the heavy load coming on to the ribs, eight additional bolts of 12m length were installed on the left wall of the bus duct No.1 at the mid height. It could be noted that the side walls of the bus ducts were supported with 6m long resin cum cement grouted bolts. After installation of additional bolts, the rate of loading decreased from 1.39t/day to 0.5t/day and load reached 73.42t at the end of 145 days. Subsequently, there was marginal increase in the load during the post excavation period. On the right side rib, the load was less than 12t. At bus duct No.2, the load on the ribs varied from 2.2t - 59.24t, whereas the load on the ribs at bus duct No.3 varied from 0.34t-16.49t. It could be noted from Fig. 4.64 that the load on the ribs at passage tunnel reached 111.28t on the left side and 76.81t on the right side. From the instrumentation data it was evident that, bus ducts have witnessed loads in the range of 0.03 to 94.28t (i.e. 0.003 - 0.92MN). Considering the sectional area of ISMB 300 (58.6cm²), the stresses acting on the ribs varied from 0.57 - 157.78MPa, whereas, the passage tunnel experienced load in the

range of 1.35 - 111.28t (i.e. 0.01 - 1.09MN). Considering the sectional area of ISMB 250 (47.5cm²), the stresses acting on the ribs varied from 2.26 - 229.7MPa.

Load observations on the rock bolts are shown in Fig. 4.65.

Fig. 4.65 Axial load on rock bolts in bus ducts and passage tunnels

At bus duct No.1, load cell on the rock bolt showed sharp increase in load and reached 32.4t. After installing the additional rock bolts nearby, the load stabilised as could be seen in Fig. 4.65. At bus duct No.2, the load on rock bolt increased to 22.38t and at other locations, there was no substantial increase in the load in the rock bolts.

Load cell data on the steel ribs at pressure shaft manifolds is shown in Fig. 4.66. Load cells were also installed on rock bolts in the pressure shaft manifold and the results are shown in Fig. 4.67. Listing of all load cell data in the steel ribs and on rock bolts in pressure shaft manifolds is given in Appendix-4.

Fig. 4.66 Axial load on steel ribs in pressure shaft manifolds tunnels

Fig. 4.67 Axial load on rock bolts in pressure shaft manifolds tunnels

At pressure shaft manifold 1, maximum load on left side was 6.01t and remained almost constant. On right side, the maximum load recorded was 26.93t. At pressure shaft manifold 4, maximum load on the left side was 33.61t during excavation period and showed stabilising trend during post excavation period. On right side, maximum load of 26.27t was recorded during post excavation period, which later decreased to about

15t. Load on the rock bolts in the manifolds did not show much variation as evident from Fig. 4.67.

During post excavation period, cracks started appearing on the walls of the bus ducts and these were vertical cracks parallel to the axis of the main caverns. These cracks could be due to the tensile stresses in the immediate vicinity of the main cavern walls. Some of the typical cracks appeared in the walls are shown in Fig. 4.68.

Fig. 4.68 Tension cracks on walls of bus ducts

Since cross tunnels were subjected to maximum principal stresses, it was expected that higher load will come on to the supports. Instrumentation results showed that steel ribs are subjected to loads in the range of 100 - 110t. Rock bolts also experienced load of more than 35t. Since rock is weak in tension, development of tensile stresses closer to the downstream wall of powerhouse cavern, resulted in tensile cracks.

4.4 NUMERICAL MODELLING

Initially, numerical modelling was done using discontinuum model using 3DEC. In this case, only major joints cutting the crown of the powerhouse cavern were chosen. However, model results did not match closely with the field observations. Analysis of the results indicated that this model could not be accepted for the following reasons:

- Rock mass around the Tala powerhouse complex is highly jointed with 5 sets of joints in addition to foliation. Average GSI value of 50 confirms this. Therefore, including few sets of joints in the model will not represent the rock mass. It is not possible to model all the joint sets in 3DEC with actual spacing.
- Presence of more than 5 sets of joints makes the 3DEC modelling not so effective.
- In the present case study, there were no specific shear zones or fractured zones, so that its effect on the cavern could be modelled using 3DEC.
- In 3DEC model, derived rock mass parameters were further reduced by the influence of joint parameters. Using laboratory tested values directly in the model could prove very conservative as all the joint sets could not be represented in the model.

Therefore, it was decided to discard the results of 3DEC modelling and consider FLAC 3D continuum modelling technique, using the rock mass parameters. Model results of FLAC-3D was further analysed and presented in this section.

4.4.1 Displacement Distribution around the Caverns

In the model, actual geometry and sequence of excavation as followed during excavation of the cavern was used. Since the excavation of the benches started after installation of the steel ribs in both the caverns, simulation studies started with excavation of crown with steel ribs as the main support (Figs. 3.30 to 3.32). To establish the validity of the model, excavation of benches was done upto bench-5 with supports and difference in convergence of walls during excavation of bench-4 and bench-5 was compared at EL-525 at RD-15, RD-65, RD-110 and RD-150 (as convergence stations at EL-525 were installed at the end of bench-4 excavation). Horizontal displacement

contours at bench-4 and bench-5 at RD-15, RD-65, RD-110 and RD-150 are given in Fig. 4.69.

Fig. 4.69 Horizontal displacement contours after excavation of bench-4 and bench-5

Convergence from the model after bench-5 was compared with the field monitoring results and are given in Table 4.26. Measured displacement at RD-15 and RD-65 were higher by 11.33% and 3.61%, whereas at RD-110 and RD-150, model predictions were higher by 9.56% and 14.4% respectively. Since percentage difference is in the range of

-11.3 to 14.4%, validity of the model was acceptable considering the variability in geology in the cavern.

Table 4.26 Comparison of model and measured convergence between excavation of bench-4 (B-4) and bench-5 (B-5)

	Upstream Wall Disp. (mm)		Downstream Wall Disp. (mm)		Total Con. (mm)		Diff.in Con. (mm)	Measured Con. (mm)	Diff. (mm)	% Diff.
	B-4	B-5	B-4	B-5	B-4	B-5				
RD-15	112.8	134.3	116.7	141.1	229.5	275.4	45.9	51.1	-5.2	-11.33
RD-65	120.4	145	120.3	149.1	240.7	294.1	53.4	55.33	-1.93	-3.61
RD-110	122.4	149.8	121.2	150.3	243.6	300.1	56.5	51.1	5.4	9.56
RD-150	120.2	139.2	126.8	150.0	247	289.16	42.2	36.9	5.3	14.40

Same model was considered for further analysis and excavation of other benches and connecting tunnels was done and supports were installed in the same sequence, as followed during construction of the caverns.

Displacement contours at RD-15, RD-65, RD-110 and RD-150 sections after complete excavation of the caverns are shown in Figs. 4.70 to 4.74. Displacements at elevations, 525, 520 and 515 are shown in Figs. 4.75 to 4.77. Displacements at other sections are given in Appendix-5.

Fig. 4.70 Displacement contours at RD-15, powerhouse cavern

Maximum displacement of 222.4mm was observed at RD-15. In this section, displacements are relatively higher on downstream wall of the cavern (Fig. 4.70).

Fig. 4.71 Displacement contours at RD-65, powerhouse cavern

Fig. 4.72 Displacement contours at RD-110, powerhouse cavern

Maximum displacements at RD-65 and RD-110 were 268.9mm and 313.4mm respectively. In this section displacements were relatively higher on the upstream side of both powerhouse cavern and transformer hall cavern (Figs. 4.71 and 4.72). At RD-150 section, maximum displacement of 317.44mm was observed in the powerhouse cavern. In this case also, displacements were relatively higher on the upstream wall of powerhouse cavern (Fig. 4.73).

Fig. 4.73 Displacement contours at RD-150, powerhouse cavern

Fig. 4.74 Displacement contours at EL-525, powerhouse cavern

At EL-525, higher displacements in the range of 275-300mm were concentrated in the unit bay area on both upstream and downstream walls except at 10-15m from the end wall. Displacements in the pillar between powerhouse and transformer hall cavern were more influenced by excavation in the powerhouse cavern as the contour of smaller displacement was shifted towards transformer hall in the unit bay area. However, in the service bay area it was almost at the center of the pillar (Fig. 4.74). Similar behaviour was observed at EL-520 also (Fig. 4.75).

Fig. 4.75 Displacement contours at EL-520, powerhouse cavern

Fig. 4.76 Displacement contours at EL-515, powerhouse cavern

Displacements observed at EL-520 were greater than displacements observed at EL-525 and EL-515 by about 10%. This was due to the presence of cross tunnels like passage tunnels and bus ducts at this elevation (Fig. 4.75). EL-515 section is just below the floor of the cross tunnels. It could be observed from Fig. 4.76 that higher displacements were concentrated near the intersection of floor of the cross tunnels and downstream wall of the powerhouse cavern.

4.4.2 Comparison of Measured and Model Convergence

Cumulative convergence of the side walls of powerhouse cavern after complete excavation was compared with convergence results from the 3D model. Convergence data from the model after excavation of bench-4 was taken as the reference and convergence at each stage was compared with measured convergence at EL-525. Fig. 4.77 compares convergence at EL-525 and Table 4.27 summarises the comparison.

Fig. 4.77 Comparison of measured and model convergence at EL-525

Table 4.27 Comparison of convergence measurements with model results at powerhouse cavern

	Convergence (mm)											
	EL-525				EL-520				EL-515			
	Measured	Model	Difference	% age Diff	Measured	Model	Difference	% age Diff	Measured	Model	Difference	% age Diff
RD-15	132.3	117.05	15.25	11.53	133.3	127.83	5.47	4.10				
RD-65	280	237.64	42.36	15.13	181.7	196.96	-15.26	-8.40	173	183.85	-10.85	-6.27
RD-110	305	334.06	-29.06	-9.53	289.4	290.91	-1.51	-0.52	276	255.58	20.42	7.40
RD-150	238.8	270.61	-31.81	-13.32	233.7	280.76	-47.06	-20.14	270	249.78	20.22	7.49

At EL-525, measured values were higher at RD-15 and RD-65 and lower at RD-110 and RD-150. RD-15 is located in service bay area (RD-0 to RD-60) where width to height ratio is 0.85, whereas, RD-65 is in unit bay area (RD-60 to RD-206.4), where width to height ratio is 0.46. This point is just 5m away from the edge of the service bay area, where height of excavation changes from 24m to 44.5m. Measured and model values were identical at RD-15 after excavation of bench-7 and at RD-65, after excavation of pits. Measured convergence was 11.53% higher than model result at RD-15 and 15.13% higher at RD-65. Both RD-110 and RD-150 are in unit bay area and model predicted 9.53% more convergence at RD-110 and 13.32% more at RD-150. The difference between predicted and monitored values were within $\pm 15\%$, which established the reliability of the model.

Similarly, bench-6 was taken as the reference for comparing the convergence at EL-520. Fig. 4.78 depicts comparison of convergence at EL-520.

Fig. 4.78 Comparison of measured and model convergence at EL-520

At EL-520, field monitored convergence values were higher than predicted values at RD-15 and at other locations, predicted values were higher than the measured values. At RD-15, measured value was higher by 4.10% against 11.53% at EL-525. At RD-65 and RD-110, both measured and model values were very close with a difference of

8.40% and 0.52% respectively. Overall difference between predicted and monitored values at three points were -8.40% to 4.10%. At RD-150, the predicted value was higher than the measured value by 20.14% against 13.32% at EL-525 (Table 4.27).

Bench-7 was taken as the reference for comparing the convergence at EL-515. Fig. 4.79 depicts comparison of convergence at EL-515.

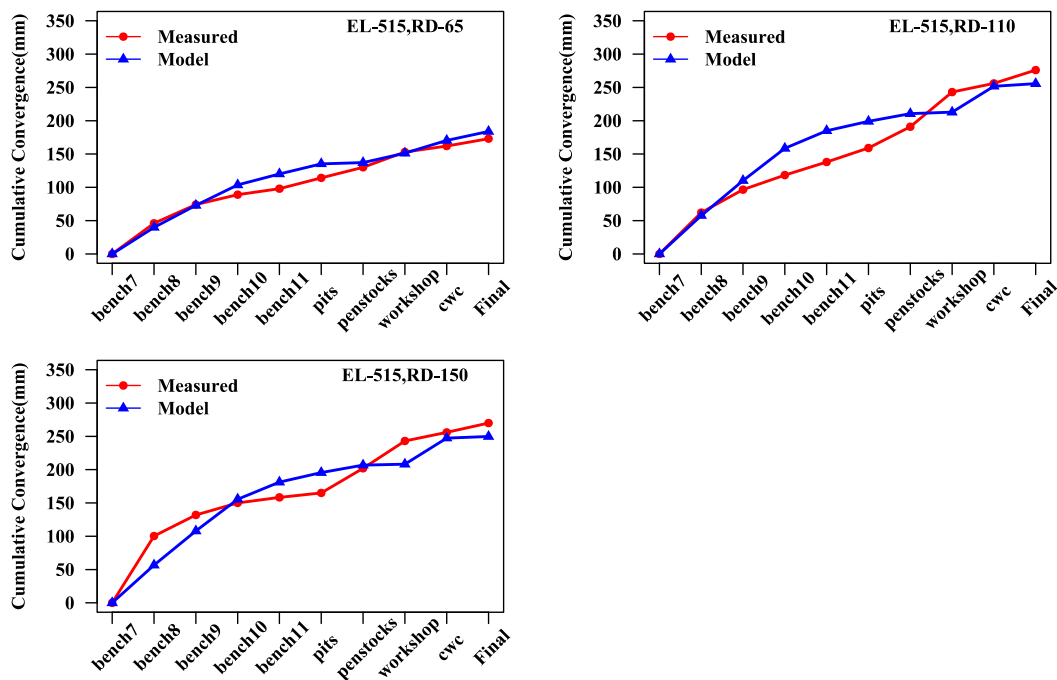

Fig. 4.79 Comparison of measured and model convergence at EL-515

At EL-515, model results were higher at RD-65 by 6.27% and at RD-110 and RD-150, measured values were higher than the model values by 7.40% and 7.49%, respectively. Measured values matched with model results very closely at six excavation stages at RD-65 and two excavation stages at RD-110 and RD-150 (Table 4.27).

Although, model and final measured convergence values match within 15% range in most cases, measured convergence values during benching stage were lower than the model predicted values. This could be due to variation in extraction rates of individual benches.

4.4.3 Stress Distribution

Principal stress contours after complete excavation at RD-15, RD-65, RD-110 and RD-150 are shown in Figs. 4.80 to 4.83.

Fig. 4.80 Principal stress contours around the caverns at RD-15

Fig. 4.81 Principal stress contours around the caverns at RD-65

Fig. 4.82 Principal stress contours around the caverns at RD-110

Fig. 4.83 Principal stress contours around the caverns at RD-150

It could be seen from Figs. 4.80 to 4.83 that maximum stress concentration was at the crown of powerhouse and transformer hall caverns. Maximum principal stress reached values of 59.37MPa at RD-15, 51.65MPa at RD-65, 53.95MPa at RD-110 and 49.99MPa at RD-150, an increase of 3.5 to 4.2 times the in-situ value. On the side walls, stresses were relaxed and values of maximum principal stress were 0.788MPa at RD-15, 1.73MPa at RD-65, 0.3MPa at RD-110 and 0.73MPa at RD-150, a decrease of 0.02 to 0.12 times the in-situ value. Similarly, intermediate principal stress (in this case vertical stress) reached maximum values of 20.93MPa at RD-15, 19.87MPa at RD-65, 23.09MPa at RD-110 and 20.56MPa at RD-150, an increase of 1.8 to 2.1 times the in-situ value. In the relaxation zone, it reached minimum values of 1.07MPa at RD-15, 0.97MPa at RD-65, -0.08MPa at RD-110 and -0.09MPa at RD-150, a decrease of 0.01 to 0.10 times the in-situ value. Induced tensile stresses appeared at the floor of powerhouse cavern at RD-110 and RD-150. Maximum values of minimum principal stresses were 12.47MPa at RD-15, 12.50MPa at RD-65, 12.71MPa at RD-110 and 13.70MPa at RD-150, an increase of 1.3 to 1.4 times the in-situ value. Tensile stresses were induced in the concrete above the steel ribs with maximum value of 2.8MPa. Tensile stresses were observed in the rock mass, particularly in the floor of powerhouse cavern due to floor heave. In general, there was an increase in principal stresses in the crown and reduction in principal stresses in the walls of cavern, which corroborates with high values of convergence recordings in the walls.

Ratio of principal stresses at final excavation stage and in-situ principal stresses would give stress concentration factor due to principal stresses. Similarly, ratio of normal stresses at final stage of excavation and in-situ normal stresses would give stress concentration factor due to normal stresses. Maximum, intermediate and minimum principal stresses at final stage of excavation are denoted by σ_{1f} , σ_{2f} and σ_{3f} , respectively and their in-situ values are denoted by σ_{1i} , σ_{2i} and σ_{3i} , respectively. Similarly, final normal stresses in X, Y and Z direction are denoted by σ_{xf} , σ_{yf} and σ_{zf} , respectively and their in-situ values are denoted by σ_{xi} , σ_{yi} and σ_{zi} , respectively. Ratios of stress concentration factors at EL-525, EL-520 and EL-515 for sections at RD-15, RD-65, RD-110 and RD-150 are given in Figs. 4.84 to 4.86.

Fig. 4.84 Distribution of stress concentration factors in cross section at EL-525

Fig. 4.85 Distribution of stress concentration factors in cross section at EL-520

Fig. 4.86 Distribution of stress concentration factors in cross section at EL-515

Stresses in the pillar between powerhouse and transformer hall

At EL-525, stress concentration factors due to maximum and intermediate principal stresses were almost equal except at RD-15, where stress concentration factor due to maximum principal stress was higher. At RD-15, maximum stress concentration factor was 2.63, whereas at RD-65, RD-110 and RD-150 it was 1.43, 1.58 and 1.20, respectively (Fig. 4.84). Higher stress concentration was observed near the edge of transformer hall at RD-15 cross section as transformer hall is only 0.5m away from end wall at this section.

Normal stresses had higher influence on the stress concentration factors in the pillar. Vertical stress had maximum influence on the pillar and maximum stress concentration factors due to vertical stress was almost two times more than that due to two horizontal stresses. At EL-525, maximum stress concentration factor due to vertical stress was 2.67 at RD-15, 2.05 at RD-65, 1.94 at RD-110 and 1.68 at RD-150. Only at edge of transformer hall stress concentration factor due to σ_x was higher at 2.87 and at all other places it was less than 1 (Fig. 4.84).

Similar observations were observed at EL-520. Maximum stress concentration factor due to principal stresses at RD-15, RD-65, RD-110 and RD-150 were 1.36, 1.52, 1.23 and 1.39 respectively. Maximum stress concentration factor due to normal stresses at RD-15, RD-65, RD-110 and RD-150 were 2.15, 2.19, 1.89 and 2.03 respectively (Fig. 4.85).

EL-515, is just 0.5m above the floor of transformer hall and height of transformer hall is equal to height of powerhouse in service bay area. In the pillar, maximum stress concentration factors were closer to transformer hall. Maximum stress concentration factors due to principal stresses were 1.53, 1.54, 1.49 and 1.79 at RD's 15, 65, 110 and 150, respectively and that due to normal stresses were 2.01, 1.83, 2.19 and 2.02, respectively. Stress relaxation near the transformer hall floor was to a lesser extent compared to other locations (Fig. 4.86).

Stresses on upstream side of powerhouse

On upstream side of powerhouse cavern, stress concentration factors due to intermediate principal stress were higher than that due to maximum and minimum

principal stresses in all cases. At EL-525, maximum stress concentration took place at a distance of 12-19m from the upstream wall. Maximum stress concentration factors due to intermediate stress were 1.62, 1.66, 1.54 and 1.42 at RD's 15, 65, 110 and 150, respectively (Fig. 4.84).

On the upstream side of powerhouse cavern, normal stresses had higher influence than the principal stresses. Here also, stress concentration factors induced by vertical stress were higher than other two normal stresses. At EL-525, maximum stress concentration due to vertical stress took place at a distance of 12-23m from the upstream wall. Maximum stress concentration factors due to vertical stress were 1.63, 1.92, 1.41 and 1.27 at RD's 15, 65, 110 and 150, respectively (Fig. 4.84).

Similar observations were observed at EL-520. Maximum stress concentration factors due to intermediate principal stress at RD-15, RD-65, RD-110 and RD-150 were 1.60, 1.66, 1.63 and 1.50, respectively. Maximum stress concentration factor due to other two principal stresses varied from 0.70 to 1.35. Maximum stress concentration factor due to vertical stress at RD-15, RD-65, RD-110 and RD-150 were more or less same, with values of 1.62, 1.76, 1.56 and 1.44, respectively. Maximum stress concentration factor due to horizontal stresses varied from 0.73 to 1.25. At EL-520, maximum value occurred at a distance of 6.6m at RD-15 and at 21m at RD's 65, 110 and 150 (Fig. 4.85).

Maximum stress concentration factors at EL-515 due to intermediate principal stress were 1.57, 1.45, 1.42 and 1.42 at RD's 15, 65, 110 and 150 and occurred at distances of 7.8m, 17.1m, 30m and 27.6m, respectively. Similarly, maximum stress concentration factor due to vertical stress varied from 1.40 to 1.50 on the downstream wall of transformer hall (Fig. 4.86).

Stresses on downstream side of transformer hall

Similar to upstream side of powerhouse cavern, at downstream side of transformer hall also stress concentration factors induced by intermediate principal stress were higher than that due to other two principal stresses. At EL-525, maximum stress concentration factors due to intermediate stress were 1.85, 1.84, 2.12 and 1.82 at RD's 15, 65, 110 and 150 respectively (Fig. 4.84). At RD-15, maximum value occurred very close to the

wall and at other places, it occurred at 12.5-13.6m from the wall. Stress concentration factor due to other two principal stresses varied from 0.93 to 1.61.

In this case also, vertical stress had higher influence on the stress concentration factor compared to that due to other two normal stresses. Maximum stress concentration factors due to vertical stress were 1.88, 1.94, 2.41 and 1.84 at RD's 15, 65, 110 and 150, respectively. At RD-15, maximum value occurred very close to the wall and at other places, it occurred at 10.5-13.6m from the wall (Fig. 4.84).

Similar observations were observed at EL-520. Maximum stress concentration factor due to intermediate principal stress at RD-15, RD-65, RD-110 and RD-150 were 1.82, 1.86, 1.86 and 1.50, respectively. Maximum stress concentration factor due to other two principal stresses varied from 0.92 to 1.29. Maximum stress concentration factor due to vertical stress at RD-15, RD-65, RD-110 and RD-150 were 1.79, 1.88, 1.86 and 1.49, respectively (Fig. 4.85). Maximum stress concentration factor due to horizontal stresses varied from 0.93 to 1.57 (Fig. 4.85). At EL-520, maximum value occurred close to wall at RD-15 and at 13.6m, 12m, and 15.3m at RD's 65, 110 and 150, respectively.

At EL-515, maximum stress concentration factor due to intermediate principal stress were 1.69, 1.61, 1.45 and 1.68 at RD's 15, 65, 110 and 150, respectively. Maximum values were close to the downstream wall of transformer hall at RD-15 and RD-150. It was at 9.1m and 15.3m from the wall at RD-65 and RD-110. Similarly, maximum stress concentration factor due to vertical stress varied from 1.41 to 1.48 on the downstream of transformer hall (Fig. 4.86).

When the cavern is oriented along maximum principal stress direction and walls are subjected to minimum principal stress (vertical stress being intermediate principal stress), stress concentration factor induced by intermediate principal stress was higher than the other two on upstream wall of powerhouse and downstream wall of transformer hall. In the pillar between powerhouse and transformer hall, stress concentration factor induced by maximum and intermediate principal stress was almost equal and that introduced by minimum principal stress was lower.

Stress analysis of pillar between powerhouse cavern and transformer hall cavern indicated stress concentration in the center of the pillar and stress relaxation at the pillar

edges (downstream wall of powerhouse cavern and upstream wall of transformer hall cavern), resulting in considerable displacement of walls, in agreement with the convergence recordings in the field. On the upstream side of powerhouse cavern, the relaxation zones were extending upto 15m (average), indicating that large displacements were taking place upto 15m depth, with maximum displacement at the upstream wall. This aspect was proved by observation of large convergence of the walls in the field. Similar phenomenon was observed on downstream side of transformer hall also.

4.4.4 Strain on the Walls of Caverns

Strain on upstream and downstream wall was calculated considering the half width of the cavern, so that areas of relatively high strains on each wall are identified more precisely. The percentage strain calculated on upstream side and downstream side of powerhouse cavern are shown in the form of contours in Fig. 4.87 and Fig. 4.88, respectively.

Fig. 4.87 Strain distribution on upstream wall of powerhouse cavern

Fig. 4.88 Strain distribution on downstream wall of powerhouse cavern

A maximum strain of 3.34% was observed on the upstream wall, between elevations 527.5 and 517, inbetween RD-95 and RD-157. On the upstream wall, strains of more than 2% were observed in unit bay area from EL-531 to EL-505 (where width to height ratio is 0.46). In the service bay area, strains were restricted upto 2% (where width to height ratio is 0.85). Maximum strain observed on downstream wall was 3.35% and observed between elevations 527 and 516 inbetween RD-76 and RD-174, where bus ducts are situated. Higher strains were concentrated near the crown of bus ducts. On downstream wall, strains of less than 2% were observed in service bay area. Results clearly indicated that when the height of excavation increases (w/h ratio decreases), unit bay area experiences higher strain.

Similarly, strain on the upstream and downstream wall of transformer hall are shown in Figs. 4.89 and 4.90, respectively, indicating a similar behaviour of rock mass.

Fig. 4.89 Strain distribution on upstream wall of transformer hall cavern

Fig. 4.90 Strain distribution on downstream wall of transformer hall cavern

4.4.5 Strength to Stress Ratio

Strength to stress ratio calculated using 3D Hoek and Brown failure criterion is shown in sections at RD-15, RD-65, RD-110 and RD-150 in Figs. 4.91 to 4.94. Tensile failures were noticed in the corners and at the floor of the powerhouse cavern (due to floor heave). Most of the surrounding rock mass had strength to stress ratio of more than two, except few isolated patches in the immediate vicinity of the walls of cavern. Overall stability of the cavern was not affected by these small patches of failed zone.

Fig. 4.91 Strength to stress ratio at RD-15, powerhouse cavern

Fig. 4.92 Strength to stress ratio at RD-65, powerhouse cavern

Fig. 4.93 Strength to stress ratio at RD-110, powerhouse cavern

Fig. 4.94 Strength to stress ratio at RD-150, powerhouse cavern

4.4.6 Effect of Cavern Orientation on Stability

A parametric study was carried out by varying the angle (Θ) between cavern axis and direction of maximum principal stress at an interval of 15° . Variation of displacement with various configurations at EL-525, EL-520 and EL-515 are shown in Fig. 4.95.

Fig. 4.95 Variation of displacement with cavern configuration

On upstream side, an increase in maximum displacement by about 28.7% was found to occur at an angle of 90° . On downstream side, increase in maximum displacement was found to be only 18.2% at an angle of 90° . Parametric study results have indicated that with an increase in angle between axis of the cavern to principal stress direction, displacements were increasing and reaching highest value at 90° orientation. Similar behaviour was observed at EL-525, EL-520 and EL-515.

Stress concentration factors at various orientations in pillar between powerhouse and transformer hall were analysed. Maximum stress concentration factors observed in the pillar with different orientations due to vertical stress and other two normal stresses are shown in Figs. 4.96 to 4.98.

Fig. 4.96 Variation of maximum stress ratio in the pillar due to vertical stress with cavern configuration

Fig. 4.97 Variation of maximum stress ratio in the pillar due to σ_{xx} with cavern configuration

Maximum stress concentration factor due to vertical stress varied in the range 1.68 to 2.25 in RD's 65,110 and 150 with maximum value at RD-65 at EL-525 at an angle of 150° and minimum at RD-150, EL-525 at an angle of zero degree. At RD-15, it varied from 2.0 to 2.90 with maximum at EL-525 at an angle of 30° and minimum at EL-515 at an angle of 165° (Fig. 4.96). Thus maximum stress concentration factor in the pillar due to vertical stress does not change significantly with cavern configuration except in the pillar near the end walls.

Maximum stress concentration factor due to σ_{xx} varied from 0.40 to 1.81 in the unit bay area and 0.74 to 3 at RD-15. That means the maximum confinement provided by σ_{xx} decreased to 0.40 times the in-situ value at an angle of 90° that may have adverse effect on the stability of the pillar (Fig. 4.97).

Fig. 4.98 Variation of maximum stress ratio in the pillar due to σ_{yy} with cavern configuration

Maximum stress concentration factor due to σ_{yy} varied from 0.73 to 1.56 in the unit bay area and 0.73 to 2.69 at RD-15 with maximum values at an angle of 75° and 90°. That means maximum stress concentration factor due to σ_{yy} (which already has highest magnitude) at 75° and 90° increased by 1.56 times the in-situ value (Fig. 4.98).

Maximum stress concentration factors due to vertical stress, observed in the upstream wall of powerhouse with different orientations and other two normal stresses are shown in Figs. 4.99 to 4.101.

Fig. 4.99 Variation of maximum stress ratio in the upstream wall of powerhouse due to vertical stress (σ_{zz}) with cavern configuration

Fig. 4.100 Variation of maximum stress ratio in the upstream wall of powerhouse due to σ_{xx} stress with cavern configuration

On the upstream wall of powerhouse cavern, maximum stress concentration factor due to vertical stress varied from 1.15 to 1.95 and effect of end wall (at RD-15) was not there. Maximum values occurred at an angle of zero degree and minimum values occurred at an angle of 90° (Fig. 4.99). Maximum stress concentration factors due to σ_{xx} varied from 0.48 to 1.55 and maximum level of destressing of rock mass in the upstream wall occurred at an angle of 90°. At RD-15 at EL-515 (floor level at service bay area), destressing was minimum at an angle of zero and 165° (Fig. 4.100). Maximum stress concentration factor due to σ_{yy} varied from 0.84 to 1.26 with maximum confinement levels going below the in-situ values from angles 60° to 120° (Fig. 4.101).

Fig. 4.101 Variation maximum stress ratio in the upstream wall of powerhouse due to σ_{yy} stress

Thus at an angle of zero degree, i.e. when the cavern was oriented parallel to maximum principal stress, maximum stress concentration factors due to vertical stress were the highest on the upstream wall of powerhouse. But at an angle of 90°, confinement provided by σ_{xx} and σ_{yy} decreased, causing instability problems in the wall.

Maximum stress concentration factors observed in the downstream wall of transformer hall cavern with different orientations due to vertical stress and other two normal stresses are shown in Figs. 4.102 to 4.104.

Fig. 4.102 Variation maximum stress ratio in the downstream wall of transformer hall due to vertical stress (σ_{zz})

Fig. 4.103 Variation maximum stress ratio in the downstream wall of transformer hall due to σ_{xx} stress

Maximum stress concentration factor due to vertical stress in unit bay area varied from 1.3 to 2.58, maximum being at RD-150 at EL-515 when the orientation angle was 90°, whereas in service bay area at RD-15 it varied from 1.38 to 2.03 (Fig. 4.102). Maximum stress concentration factors due to σ_{xx} in unit bay area varied from 0.73 to 1.62, and in service bay area at RD-15 it varied from 0.88 to 2.26 (Fig. 4.103). Similarly, maximum stress concentration factor due to σ_{yy} in unit bay area varied from 0.96 to 1.59 and in service bay area it varied from 0.97 to 2.27 (Fig. 4.104). Confinement levels provided by σ_{xx} and σ_{yy} were greater on downstream wall of transformer hall than on the upstream wall of powerhouse cavern.

Fig. 4.104 Variation maximum stress ratio in the downstream wall of transformer hall due to σ_{yy} stress

4.4.7 Sensitivity Analysis

In this study, four independent variables - cohesion, friction angle, elastic modulus and Poisson's ratio were taken into consideration to analyse their effect on final convergence predicted from the modelling study. Independent parameters were changed from +20% to -20% at a step of 5%. Results of sensitivity analysis are listed in Table 4.28.

Table 4.28 Results of sensitivity analysis

		Predicted Convergence (mm)				Percent Change with Reference to Base Model			
RD & EL	%	C	Φ	E	ν	C	Φ	E	ν

C – Cohesion; Φ = Friction angle; E = Elastic Modulus; ν = Poisson’s ratio

EL-525, RD-65: Results from the analysis are presented by tornado diagram at EL-525 at RD-65 as given in Fig. 105. At this location, predicted convergence was 424.7mm, when the friction angle was reduced by 20%, and 161mm when friction angle was increased by 20%. With other parameters, predicted convergence was lesser as seen in Fig. 4.105 and Table 4.28.

Fig. 4.105 Tornado diagram of sensitivity analysis at RD-65, EL-525

EL-525, RD-110: Tornado diagram at EL-525, RD-110 is shown in Fig. 4.106. Decreasing friction angle by 20% increased predicted convergence to 581.87mm against the base model value of 331.1mm. Increasing friction angle by 20% resulted in decrease of convergence to 218.13mm. The other parameters had relatively less influence as shown in Fig. 4.106 and Table 4.28.

Fig. 4.106 Tornado diagram of sensitivity analysis at RD-110, EL-525

EL-525, RD-150: Tornado diagram at EL-525, RD-150 is shown in Fig. 4.107. Reduction of friction angle by 20% resulted in increased convergence to 571.8mm against the base model value of 325.2mm. The convergence decreased to 218.13mm when friction angle increased by 20%. Other parameters had less influence as shown in Fig. 4.107 and Table 4.28.

Fig. 4.107 Tornado diagram of sensitivity analysis at RD-150, EL-525

Sensitivity analysis results clearly indicated that friction angle is the most sensitive parameter among the all considered parameters. When the friction angle is reduced by 20%, predicted convergence increased by an average of 76.2%. When the cohesion is reduced by 20%, predicted convergence increased by an average 32.4%. Decreasing the elastic modulus by 20% increased the predicted convergence by an average of 23.3%. When Poisson’s ratio is reduced by 20%, there was an increase of only 11.7% in predicted convergence (Figs. 4.105 to 4.107). Similar results were obtained when the parameters were increased by 20%. Predicted convergence decreased by 33.9% (average) when friction angle was increased by 20%. It was 20.9% (average) for cohesion, 15.6% (average) for elastic modulus and 11.4% (average) for Poisson’s ratio. Thus, decreasing the friction angle has most influence on the predicted convergence in the model (Table 4.28). Cohesion, elastic modulus and Poisson’s ratio were less sensitive in that order.

CONCLUSIONS

Behaviour of large caverns in Himalayas was studied with field investigations and 3D numerical modelling. Research study provided good understanding of the response of surrounding rock mass to the construction of large caverns in typical Himalayan geological condition. Following conclusions were drawn from this study:

1. MRMPBX data indicated significant influence of side slashing in the crown (accounted for 71-88% of total displacement) on the stability of the crown and super incumbent rock mass. There was clear indication of joint separation taking place even upto 10m above the crown, indicating the requirement of long rock bolts of minimum 12m length. Strains derived from MRMPBX observations in the crown were more than 1%.
2. In the crown, load cells on rock bolts recorded upto 70% of yield load and loss of bolt loads were recorded with appearance of cracks in the roof. Complete utilisation of bolt load was not possible due to shorter length (8m) and joint separations above the bolted horizon.
3. Rate of increase in axial load in the steel ribs was influenced to maximum extent by benches within 1.05 times the width of the cavern. Time taken for excavation of each bench also had considerable influence on the rate of increase in load on the steel ribs.
4. Monitoring of cumulative convergence of upstream and downstream wall of powerhouse cavern showed convergence of about 135mm in the service bay area and 200-355mm in the unit bay area. Calculated strains were 0.92 to 1.74% in the unit bay area and upto 0.66% in the service bay area. During excavation of powerhouse cavern, about 88% of total convergence took place and about 12% was recorded during post excavation period. In transformer hall cavern, maximum strain of 1.02% was recorded with width to height ratio of 0.65.
5. Rock bolts in the walls of powerhouse cavern recorded load upto 45t. On downstream wall most of the rock bolts at higher elevations experienced about 85% of final load during benching, while most of the bolts at lower elevations experienced about 30% of final load during post excavation period. On

upstream side, bolts at almost all elevations experienced about 87% of final recorded load during the excavation of benches and reduction of load in some cases after complete excavation and during post excavation period.

6. Strains in the rock bolt measured with instrumented bolt showed that there was increase in strain at 1m depth in all cases. In some cases, there was an increase in strain upto 4 to 5m depths. At 11m and 12m depths, there was decrease in strain in all cases. This behaviour was consistent with other studies quoted in the literature.
7. Monitoring of load in the steel ribs in cross tunnels indicated development of load in the range of 100-110t (as cross tunnels were subjected to maximum principal stresses) and load on the rock bolts in cross tunnels were also very high (>35t). Vertical cracks parallel to axis of the powerhouse cavern developed in the walls of bus ducts due to tensile stresses in the downstream wall of powerhouse cavern.
8. Continuum modelling with FLAC-3D represented the behaviour of rock mass and caverns very well, compared to discontinuum modelling with 3DEC.
9. Predicted convergence from the models developed compared well with the field monitored values within 15% at most of the places. Although, there was close agreement between model and field values, measured convergence values during benching stage were lower than the model predicted values. This could be due to variation in extraction rates of individual benches.
10. Displacements observed at EL-520 were greater than displacements observed at EL-525 and EL-515 by about 10%. This was due to the presence of cross tunnels like passage tunnels and bus ducts. Higher displacements were concentrated near the intersection of floor of the cross tunnels and downstream wall of the powerhouse cavern.
11. In general, there was increase in principal stresses in the crown and reduction in principal stresses in the walls of cavern, which corroborates with high values of convergence recordings in the walls.
12. Analysis of stress concentration factors in the pillar between powerhouse and transformer hall indicated factors due to maximum and intermediate principal stresses were almost equal (varied from 1.20 to 1.58) except at end wall section

of transformer hall, where stress concentration factor due to maximum principal stress was higher (2.63). Normal stresses had higher influence on the stress concentration factors in the pillar. Vertical stress had maximum influence on the pillar and maximum stress concentration factors due to vertical stress is almost two times more than that due to two horizontal stresses.

13. Numerical modelling results indicated maximum strain of 3.34% on the upstream wall and 3.35% on downstream wall. On downstream wall maximum strain was observed near the bus ducts. Higher strains were concentrated near the crown of bus ducts. Results clearly indicated that when the height of excavation increases (w/h ratio decreases), excavation experiences higher strain.
14. Most of the surrounding rock mass had strength to stress ratio of more than two, except at few isolated patches in the immediate vicinity of the walls of cavern.
15. Parametric study conducted on orientation of cavern with respect to maximum principal stress direction showed that, maximum displacement increased by 28.7% at an angle of 90° on upstream side and 18.2% on downstream side. Maximum stress concentration factor in the pillar due to vertical stress does not change significantly with cavern orientation.
16. When the cavern is oriented parallel to maximum principal stress, maximum stress concentration factors due to vertical stress were the highest on the upstream wall of powerhouse.
17. Sensitivity analysis results clearly indicated that friction angle was the most sensitive parameter in prediction of convergence followed by cohesion, elastic modulus and Poisson's ratio in order.
18. Combined analysis of field investigations and 3D modelling results and correlation between the two could explain the behaviour of the cavern and surrounding rock mass in a comprehensive manner under a Himalayan geological setup.

Suggestions for Future Studies

1. Himalayan rock mass consisting of phyllites and phyllitic quartzite are susceptible to creep behaviour, which is evident from the continued

convergence of side walls in the cavern in this study. This aspect could not be incorporated in the current numerical model. An appropriate visco-elasto-plastic model may be developed incorporating the creep behaviour of such rock types.

2. Stresses in the pillar between the two caverns may be monitored in the field, preferably in three principal stress directions.
3. Similar field studies and numerical modelling studies may be extended to other upcoming caverns in Himalayas, so that comparison could be drawn and guidelines could be developed.
4. Such studies may be done in other geological setups for comparing the behaviour of rock mass and large caverns under various conditions.

APPENDIX -1

Table 1. Wedge formation at the powerhouse cavern with different sets of joints.

Intersection of Joints	Wedge No.	Plunge	Trend	Analysis of Joint (Wedges, Toppling and Sliding)		
				Upstream Wall	Downstream wall	Remark
J1 & J2	W1	23°	356°	Favorable	Favorable	Stable due to $\phi > 23^\circ$ (plunge)
F1 & J2	W2	41°	330°	Favorable	Favorable	Minute unfavourable to D/S wall
J4 & F1	W3	31°	303°	Favorable	Favorable	J4 is very unfavourable to Upstream Vertical Wall
J2 & J4	W4	53°	280°	Occasional Unfavourable	Favorable	J4 is very favourable to Downstream Vertical Wall
J2 & J5	W5	41°	235°	Highly Unfavourable	Favorable	Unstable due to $\phi < 41^\circ$ (plunge) and plunge direction perpendicular to face, toppling may possible
J2 & J3	W6	04°	198°	Favorable	Favorable	Very gentle plunge
J4 & J5	W7	54°	179°	Occasional Unfavourable	Favorable	Few chunks may topples/slide at the U/S wall
J3 & J4	W8	32°	157°	Favorable	Favorable	Minute toppling at the U/S wall
J1 & J4	W9	19°	150°	Favorable	Favorable	Very gentle plunge parallel to the U/S wall
J1 & J5, J1 & J3, and J3 & J5	W10	40°	132°	Favorable	Favorable	Minute toppling may possible at the D/SW (Sets of wedge form at the with minor variation of the trend/plunge)
J3 & F1	W11	25°	059°	Favorable	Favorable	Stable due to $\phi > 25^\circ$ (plunge)
J1 & F1	W12	44°	016°	Favorable	Favorable	Minor unstable U/S wall

J4 (65°/230°) indicates highly slide failure and intersection of J5 and J2 indicates wedge failure with plunge/trend (W5, 41° / 235°) at the upstream vertical wall. Downstream wall indicates minor toppling/slide by joint J1(60°/072°) and indicates rare wedge failure (W12, 44°/016°). Instability problems may be higher on upstream vertical wall compared to downstream vertical wall.

Table 2. Details of joints mapped and used in 3DEC model.

International Symposium

Sripad, R. N., and Sastry, V. R., 2014. Behaviour of cross tunnels in large underground cavern- A case study, International symposium ROCK MECHANICS 2014-Present Technology and Future Challenges, 20--22 August, New Delhi

Sripad, R.N., and Sastry, V.R., 2017. Assessment of stability of large caverns in Himalayas using 3D Numerical Modelling” International Conference on NexGen Technologies for Mining & Fuel Industries (NxGnMiFu-2017) February 15-17, 2017, Vigyan Bhawan, New Delhi, India.

CURRICULUM VITAE

Name : Sripad Ramachandra Naik
Contact No. : +91 9449225973
E-mail : sripad_naik@yahoo.com, sripadnaik@gmail.com
Date of Birth : 02-09-1968
Permanent Address : No. 49, Gurukrupa
1st Block, 3rd Street, 1A Cross
Prakruthi Township
Bengaluru – 560 043
Correspondence Address : Numerical Modelling Department
National Institute of Rock Mechanics
Eshwar Nagar, Outer Ring Road
Banashankari 2nd Stage
BENGALURU – 560 070

Mr. Sripad R Naik is a graduate in Mining Engineering from NIT, Surathkal in 1990 and acquired his masters from IT, BHU. Mr. Sripad joined National Institute of Rock Mechanics in the year 1992 and presently he is Head, Numerical Modelling Department. He has expertise in numerical modelling and instrumentation in the areas of mining and civil engineering. He has worked on many challenging problems in the area of hydroelectric projects, coal mine method of working and instrumentation and subsidence modelling. Substantial experience in sophisticated research techniques and technologies, particularly in the area of 3D modeling of underground structures, slopes. Expert in planning, design and execution of geotechnical instrumentation work for mining and hydroelectric projects. He has published 31 technical papers in journals and national and international conferences.
