DECLARATION

by the Ph. D Scholar

I hereby declare that the Research Thesis entitled “**Assessment and Evaluation of Pongamia Pinnata Oil as an Alternative Fuel for Mine equipment**” which is being submitted to the **National Institute of Technology Karnataka, Surathkal** in partial fulfillment of the requirements for the award of the Degree of **Doctor of Philosophy in Mining Engineering** is a bonafide report of the research work carried out by me. The material contained in this Research Thesis has not been submitted to any University or Institution for the award of any degree.

Balaji Rao K

**DEDICATED
TO
MY FAMILY,
MY TEACHERS AND
MY FRIENDS**

ACKNOWLEDGEMENT

I am indebted to my supervisors Dr. B. M. Kunar, Assistant Professor, and Prof. Ch. S. N. Murthy, Professor-HAG, National Institute of Technology Karnataka (NITK), Surathkal, for their excellent guidance and support throughout the research work. Their valued time, constant encouragement, help and review of the entire work during the investigations are invaluable.

I wish to thank all the members of the Research Program Assessment Committee (RPAC), including Prof. M. Govinda Raj, Professor, Department of Mining Engineering, NITK, Surathkal and Dr. Kumar G N, Associate Professor, Department of Mechanical Engineering, NITK, Surathkal for their unbiased appreciation and criticism all through this research work.

I wish to express my sincere thanks to Prof. Harsha Vardhan, Associate Professor, Head and DRPC Chairman, Department of Mining Engineering, NITK, Surathkal and former HODs Dr. M. Auna, Dr. K. Ram Chandar, Prof. M. Govinda Raj and Prof. V. R. Sastry, for providing the departmental facilities, which ensured the satisfactory progress of my research work.

I express my sincere gratitude to, Dr. Anup Kumar Tripathi, Assistant Professor, and Dr. Sandi Kumar Reddy, Dr. Srikant Lamani, Assistant Registrar, Department of Mining Engineering, NITK for their constant encouragement during my research work.

I express my heartfelt thanks to Sri. Santosh, Sri. Surender, Sri Satish, Smt. Bharathi, Smt. Chandrakshi and Smt. Gayathri, Department of Mining Engineering, NITK, Surathkal who helped me in one way or the other during the course of my work. Also, I thank NITK, Surathkal, for providing financial assistance and all the necessary facilities to make this research peaceful. I also thank the Department of Chemical Engg., and Department of Mechanical Engg., NITK, for providing experimental facilities.

I owe my deepest gratitude to The Hutti Gold Mines Limited (HGML), Karnataka, for giving permission to collect data for my research work. I also owe my deepest gratitude to Sri. Prakash, I/c Executive Director, HGML, Karnataka, Sri. Sikender, Sri. Dean Derrick, Sri. Elango Ramchandra, Sri. Kumaresh A, Sri Suresh Tambe, Sri. Prakash Bandenur, Sri. Prashant D, Sri Manjunath Kadler, Sri. Zakeer Hussain, Sri. Safiulla Khan, Sri Manjunath Ellappa, Sri.

Raghavendra, Sri. Ravi Kumar, Sri. Manjunath T S, of HGML, Karnataka for their kind help during collecting data in the Mine.

I would like to thank my friends Dr. Harish Kumar N S, Dr. N V Sarathbabu Goriparti, Dr. Vijay Kumar S, Mr. Harish H, Dr. Gayana B C, Mr. Sridhar S, Dr. Lakshmi Narayana S, Dr. Vijaya Raghavan P Mr. Mohit Bekal, Mr. Eshwaraiah, Dr. Balaraju Jakkula, Dr. Ch. Vijay Kumar, Mr. Bharath Kumar S, Mr. Pudari Harish, Mr. Gurram Dileep, Mr. Raghunath Reddy, Mr. Sahas Swamy, Mr. Bojja Shiva Kumar, Mr. Ram Mohan Perumalla, Mr. Anil Nayak, Mr. Sasi Kiran, Mrs. Chenna Basamma and Mr. Tejeswaran K M, for their countless help during my research work. I Specially Thank Dr. Jagadish for his help during the experimentation.

I would like to share this moment of happiness with my father Late Mr. K Krishna Murthy, my mother, Late Mrs. Vimala Bai K, my elder Brother Mr. Satish Rao K, my younger brother Mr. Sajjan Rao K, my sisters in law Mrs. Gayathri and Mrs. Sirisha my father in law Mr. K H Jayaprakash, my mother in law Late Mrs. Shobha J P, my wife Mrs. Seema K J, my dearest little masters, Devashree-Kaushal, Humangh-Lisha, and Yashica-Lian Sai, for all the sacrifices and compromises they have made during the tenure of my Ph. D work.

I also thank my cousin brothers, sisters, and elder parents who have been continuously supporting me during the course of my research work.

I am sure I have forgotten someone. I assure you that this is a shortcoming on my part and not on yours. I beg you to forgive me for my oversight.

(Balaji Rao K)

ABSTRACT

The growing population has demanded to need more power generation. The present era relies mainly on fossil fuels as solid and liquid power sources. The demand for more power can lead to the exhaustion of fossil fuels. This also has given rise to a search for an alternative fuel source. Liquid fuels can readily be supplemented using other alternative fuel sources, including ethanol, natural gas, electricity, hydrogen, propane, methanol, P-series fuels, and biodiesel. Biodiesel can be used as a supplement to diesel in the form of blends. *Pongamia pinnata* is one of the most popular sources of biodiesel in South India.

In the present study, *Pongamia pinnata* is introduced as a biodiesel source in different forms, namely raw form, ester form, and combined form. i.e., Raw pongamia oil (RPO), methyl ester of Pongamia oil (MPO), a combinational form of methyl esters of Pongamia and waste cooking oil (MPWO), methyl esters of Pongamia pinnata and waste cooking oil (MWO). Samples were prepared with blends varying from 0% to 30% in increments of 5% volumetrically, and these samples were referred to as base biodiesel blends. A similar set of samples were prepared with an additional 10% volume of ethanol and acetone to the base biodiesel blends by reducing the volumetric contribution of diesel. The total sample size was 75, including diesel.

For each prepared sample, property tests were performed to identify the density, kinematic viscosity, and calorific value. A deviation was computed with reference to diesel. It was found that the RPO showed the largest deviation as far as the properties were concerned, which were found to be 1.66% lower, 13.24% lower, and 1.81% for density, Kinematic viscosity, and calorific value, respectively.

Further, the engine test was carried out on a single-cylinder four-stroke diesel engine. The engine speed was kept constant (1500 rpm), and the engine load varied from 5% to 100% in increments of 25% of the engine load. i.e., the engine speed was maintained constant for each engine load, and the same was followed for all 75 samples. The time taken for 10cc fuel consumption and the corresponding emissions at each engine load was recorded. Four of the emission parameters were observed, namely carbon monoxide (CO), Carbon dioxide (CO₂), unburnt hydrocarbons (UHC), and oxides of Nitrogen (NO_x). The mass of fuel consumed

(MF), brake thermal efficiency (BTE), and brake-specific energy consumption (BSEC) were calculated.

The effects of blending on the performance and emissions of the engine were evaluated by plotting a scatter graph. The average deviations of performance and emission parameters were found. The average deviations were measured by referencing each base biodiesel blend and its ethanol and acetone additions. BTE and BSEC of diesel-ethanol (DE) were found to be near to the BTE and BSEC of diesel, with deviations (higher) of 2.59% and 2.33%, respectively. DE is considered the best alternative for diesel in terms of efficiency and energy consumption. RPO is considered the poorest source regarding efficiency and energy consumption, with deviations (Lower) of 32.73% and 41.4%, respectively. All biodiesel blends showed lower CO and UHC emissions, exhibiting higher CO₂ and NO_x. RPE (raw Pongamia-ethanol) blends showed better CO and UHC with deviations (Lower) of 57.47% and 51.1% and poorer CO₂ and NO_x with deviations (higher) of 49.16% and 172.67%.

Statistical analysis was performed to predict the performance and emissions of the engine. Regression modelling (multivariate) and ANOVA analysis were used to develop regression equations and identify the significant parameters. The parameters blend, load, density, kinematic viscosity, calorific value, and mass of the fuel consumed were considered input parameters. The output parameters include BTE, BSEC, CO, CO₂, UHC, and NO_x. It was observed that the regression models showed a performance of more than 70% R-squared values at a confidence interval of 95% in predicting the performance and emissions of the engine. Blend and load on the engine were considered the most significant parameters.

Prediction studies were also performed using the ANN technique. The number of neurons varied from 4 -10, and a two-layered perceptron neural network was chosen for the analysis. TRAINLM and LEARNGDM were used as training and learning algorithms. The Transfer function is TRANSIG. Each neuron's Root mean squared error (RMSE) value was computed. The best model was evaluated to be the one with the least RMSE. With 375 data sets, 263 were used for training the model, and the remaining 112 were used for testing and validating the model. 50% of the remaining data is shared equally for each testing and validation. An MLPNN network, the optimised model for predicting BTE, BSEC, CO, and NO_x, was found to have 6

neurons. The best model for predicting the UHC and CO₂ is the one with 5 neurons with R² value of 0.99 for all training, testing, and validation.

Field studies were conducted in one of the esteemed Underground metal mines in southern India. A mine Tipper was selected to conduct the test with 20% of the blends of base biodiesel. Two conditions, idle and high idle, were implemented to study the variations. The four emission parameters studied were NO, NO₂, NO_x, and CO. The observations were similar to experimentation, and the deviations are estimated. RPO reduced CO emissions of the engine. Alternatively, increasing nitrogen emissions. The deviations of RPO compared to diesel were 29.5% and 50.74%, with diesel at both idle and high idle conditions for CO, respectively. The deviations measured are 29.5% and 33% at both idle and high idle conditions for NO_x, respectively.

NOMENCLATURE

RPO: Raw Pongamia Pinnata Oil

MPO: Methyl esters of Pongamia Pinnata

MWO: Methyl esters of Waste cooking oil

MPWO: Methyl esters of Waste cooking oil and Pongamia pinnata oil

RPA: Raw Pongamia oil with Acetone

RPE: Raw Pongamia oil with Ethanol

MPE: Methyl esters of Pongamia Pinnata with Ethanol

MPA: Methyl esters of Pongamia Pinnata with Acetone

MWE: Methyl esters of Waste cooking oil with Ethanol

MWA: Methyl esters of Waste cooking oil with Acetone

MPWE: Methyl esters of Waste cooking oil and Pongamia pinnata oil with Ethanol

MPWA: Methyl esters of Waste cooking oil and Pongamia pinnata oil with Ethanol

DE: Diesel with Ethanol

DA: Diesel with Acetone

CO: Carbon Monoxide

CO₂: Carbon Dioxide

SO₂: Sulphur Dioxide

NO: Nitrous Oxide

NO_x: Oxides of Nitrogen

NO₂: Nitrogen Di oxide

P-Value: Probability Value

T-Value: T-Test Values

R² or R-Sq: R-squared Value.

BTE: Brake thermal Efficiency

BSEC: Brake Specific Energy Consumption

BSFC: Brake Specific Fuel Consumption

PP: Pongamia Pinatta

CHAPTER 1

INTRODUCTION

1.1 Alternate fuels

The global fossil fuel crisis and emissions problems have led to the investigation of alternative fuels (Shahir et al. 2014). According to the report “Clean Cities” in June 2009, alternative fuels are any materials or substances that can be used as fuels, apart from fuels like fossil fuels, nuclear materials, and synthetic radioisotope fuels from nuclear reactors. The top eight alternate fuels are ethanol, natural gas, electricity, hydrogen, propane, methanol, P-series fuels, and biodiesel.

1.2 Need for alternate fuels for mining industries

Increased mining activities, frequent use of fossil fuels, and equipment fuelled using petroleum products contribute to the emission of greenhouse gases (GHGs). The mining industry uses diesel equipment, including load haul dumpers (LHD), Side discharge loaders (SDL), shovels, graders, tractors, and explosive vans.

Inflation in diesel prices and the availability of crude oil to produce diesel are significant concerns. The amount of oil exploration for the forthcoming decades may reach the highest peak due to the increasing population of the world and a relative increase in the transportation system relying on the energy sectors for more fuel. As "The Hindu" reported on "26th August 2018", Fortescue Metals of Australia, the world's fourth-largest iron ore miner, considers fuel an inflation driver to increase production margins. With the increase in production, the machinery for a particular mine industry also increases.

The second major concern for using alternative fuels in the mining industry is the environmental problems from diesel use. As per the Central pollution control board (CPCB) guideline on emissions, the sulfur content in diesel was limited to 0.035% in 2010. Further, it was 0.05% during 2005-10, 0.25 during 2000-2005, and 0.5% during 1996-2000. Some alternative fuels possess zero sulfur content; as a form of alternative fuel, biodiesel possesses lesser to zero sulfur content than diesel. Apart from this, the emissions arising from the outlet of diesel engines contain Carbon monoxide (CO) and

Unburnt Hydrocarbons (UHC), which contribute as a part to air pollution (Shahir et al. 2015), thereby enhancing the demand for the use of alternative fuels instead of diesel. The outcome of excess emissions using fossil fuels has resulted in global warming. As per the Indian climate emergency institute, global warming is synonymous with the enhanced greenhouse effect, increasing the number of greenhouse gases surrounding the earth's atmosphere, which leads to the trapping of more and more solar radiation and therefore increases the planet's overall temperature.

The third primary concern to using alternative fuels is that economy is involved in importing fuels, as per the web reports of "Veolia" The economy is classified into two types: conventional economy and circular economy. In a conventional economy, everything is linear from cradle to extraction, production, and disposal. In the circular economy, consumption patterns are designed to mirror the cyclical approach of natural ecosystems. With over 1.3 billion people and a GDP growth of 7% annually, India faces new resources and energy consumption challenges. It has become necessary to control GHG emissions, waste generation, pollution, and erosion of natural capital. That is why the circular economy model is an opportunity for India to reach a long-term prosperity economy. With the implementation of the circular economy, even mine wastes can be recycled to improve the economy further.

1.3 Why *Pongamia pinnata* (PP) and its forms as alternative fuels

An ecological restoration approach is beneficial for reclaiming land degraded by mining (Srivastava et al. 2014); most degraded lands are used for agriculture and forestry purposes. Trees and shrubs provide permanent vegetation cover on mine-degraded sites with little or no aftercare. Trees can improve soils through numerous processes, including maintenance or increasing soil organic matter (SOM) (Ahirwal et al. 2017). Several fast-growing, nitrogen-fixing, and high bio-masses-yielding tree species were tested for growth on the overburden slope. *Pongamia pinnata* is one of the best species that can be grown on slopes of the overburden (Singh A. N & Singh J. S. 2006); This implies that *Pongamia pinnata* trees can be vegetated on degraded lands to improve the productivity of *Pongamia pinnata* oil.

Pongamia trees can grow on roads, canals, and bordering portions of farmland with minimal care. Its seeds contain 28% to 34% of the oil; they are not edible. Up to 99%

biodiesel is obtained through transesterification. It can grow well in soils of low agricultural productivity, typically characterised by low water availability, low nutrient content, and high salinity (Dwivedi and Sharma 2014).

Alternative fuels are prepared using different edible and non-edible sources, but the fuel prepared to replace diesel must have similar characteristics or be the same as diesel. Many researchers have contributed to large numbers in the development of alternative fuels; Pongamia, as a fuel source, can be used as a supplement to diesel (Dwivedi G. & Sharma M. P. 2014). Pongamia pinnata, as an alternative fuel, is used in different forms. These include raw, ester, and combinational forms. The major difficulty in using the raw oil form is that the oil's viscosity is higher, leading to prolonged ignition and combustion (Zaharin et al. 2017). Hence the present study is carried out by blending the raw form of Pongamia pinata with diesel and other emulsifying agents in various blending ratios.

The other form of using Pongamia pinnata is the ester form. Because of the higher viscosity of vegetable oils, combustion of vegetable oils in IC engines is difficult. There are different processes available for reducing the viscosity of oils. Transesterification converts the oil into biodiesel, yielding max biodiesel (Balat M. and Balat H. 2010). Transesterification converts oil to biodiesel by treating the oil with an alcohol such as methanol, ethanol, and higher alcohols in the presence of an acid (Sulfuric acid) or a base catalyst (sodium hydroxide or potassium hydroxide) and subjected to a temperature.

With the use of a single type of biodiesel produced from various vegetable oils, the economy of the food supply is disturbed. Hence, an even application of biodiesels from multiple sources can provide a better solution (Gui et al. 2008). With this perspective, the present study is proposed to combine biodiesels, preferably methyl esters, from two different sources: waste cooking oil (MWO) and Pongamia pinnata oil (MPO). The advantage of preparing this mixture is that waste cooking oil's raw material cost is less than vegetable oil's yield cost. Also, the advantage of using Pongamia pinnata is that it may not disturb the economy of the food supply to a large extent as it is non-edible. The other benefit of Pongamia pinnata is the derived waste after collecting oil from the seeds, i.e., fertilisers, animal feeds, and medicines for skins. The kernels of Pongamia pinnata seeds can also be used to produce compost, soaps, and other byproducts of glycerin. Combining MWO and MPO can reduce the cost of MPO, as the raw material cost of waste cooking oil is lesser than the MPO yield.

The usage of methyl esters fuels in a diesel engine results in an increased NO_x (oxides of nitrogen/ nitrous oxide) emission, decreased unburnt hydrocarbons, and carbon monoxide (Shahir et al. 2015). Further, to regulate the NO_x emission, studies by earlier researchers were carried out using different emulsifying agents (Yusri et al. 2017). The present study also involves the emissions investigation using two different emulsifying agents, i.e., ethanol and acetone.

Statistical analysis helps researchers to determine the best optimal solutions for predicting output variables based on the input variables. ANOVA (Analysis of variance) is one such test that allows studying the Effect of parameters on the responses of the output variable, and the analysis indicates whether a particular parameter/ input has significance on output.

Some authors have used the RSM (Response Surface Methodology) approach to find optimum results through the importance of input parameters on output (Saravanan et al., 2017). In the present study, statistical analysis was carried out to understand the Effect of blending and engine loading on the performance and emission of the engine. The present study also identifies the relationship of input parameters: density, kinematic viscosity, calorific value, blend, the mass of fuel consumed, and engine load with response variables, namely specific energy consumption, brake thermal efficiency, and engine emission characteristics.

Artificial neural networks (ANNs) are biologically inspired computer programs that simulate how the human brain processes information. ANNs gather their knowledge by detecting patterns and relationships in data, and they learn (or are trained) through experience, not programming (Agatonovic-Kustrin and Beresford 2000). The ANN comprises hundreds of unique units, artificial neurons, or processing elements (PE) connected with coefficients (weights), constituting the neuronal structure in layers. ANN modelling predicts brake thermal efficiency and brake-specific energy consumption based on emission parameters, blending, and loading (Shivakumar et al. 2011). The present study also predicts energy consumption and brake thermal efficiency using ANN.

1.4 Thesis outline

Based on the literature review and to fulfill the research gap, the thesis is structured as follows:

Chapter 1

The introduction includes the alternative fuels' origin, types, needs, and applications in mining engineering.

Chapter 2

The chapter includes a comprehensive literature review of the topics covered in the proposed research work, including the different fuels, statistical techniques, ANN modelling, and applications in Mining Engineering.

Chapter 3

This chapter presents an experimental methodology, including the equipment and specifications. The chapter also describes the standards applied for measuring the properties of the prepared alternative fuels. A brief description of the experimentation methodology is also illustrated. A draft of the sample preparation chart is also presented.

Chapter 4

The chapter outlines the results of the experimentation. The Effect of loading and blending of alternative fuel in different forms is studied. The chapter also describes the engine performance and emission variations due to adding ethanol and acetone. A comparison study is carried out to identify the deviation in the engine's performance and emissions fueled with biodiesel blends from diesel.

Chapter 5

Presents the development of regression models to predict the performance and emissions of the engine. ANOVA analysis is performed to identify the most significant factors of the model.

Chapter 6

Outlines the ANN method of predicting the engine's performance and emissions. Based on load, blend, and properties of the fuel.

Chapter 7

The chapter introduces the applications and emission studies of implementing biodiesel blends in a Mine tipper.

CHAPTER 2

LITERATURE REVIEW

Over the past two decades, the research has contributed extensive data on alternative fuels and their applications in IC engines. Further, a detailed literature review is carried out to ease and interpret critical factors related to using alternative fuels, emulsification, and additive addition. The literature review is carried out considering four categories, namely.

- 1) Use of alternatives to diesel fuels in the global scenario.
- 2) Various emulsifications on diesel and alternative fuels.
- 3) Applications of biodiesel in Mining Industries.
- 4) Application of Regression and ANOVA to develop a prediction model for engine performance and emissions.
- 5) Application of ANN prediction modelling for engine performance and emissions.
- 6) Use of biodiesel in the mining industry.

2.1 Use of alternatives to diesel fuels in the global scenario

Sureshkumar et al. (2008) investigated the performance and emissions of SCFS diesel engines using *Pongamia piannata* methyl esters blends. The study concluded that up to 40% blend could be used for better efficiency, fuel consumption, and reduced emissions, similar to diesel.

Qi et al. (2009) studied the performance and emissions of SCFS diesel engines using soybean methyl ester blends. The authors' observation found properties varying from diesel BSEC (Brake specific fuel consumption) was high, similar output power as that of using diesel, emissions CO, UHC, NO_x, and smoke were reduced by 27%, 27%, 5% and 52% respectively as compared to diesel.

Godiganur et al. (2009) studied the performance and emissions of a Cummins 6 BTA 5 turbocharged engine using blends of mahua biodiesel. The authors concluded that Mahua biodiesel could be safely blended with diesel up to 20% without significantly affecting the engine performance and emissions and thus could be a suitable alternative fuel for heavy-duty engines.

Kalam et al. (2011) studied the performance and emission of waste cooking oil of palm and coconut oil blends on the MCFS engine. The author concluded that 5% blending coconut and palm fuels showed a reduced brake power of 0.7% and 1.2%, respectively, compared with diesel, reduced CO by 7.3% and 21%, respectively, and decreased HC by 23% and 17%, respectively, with blend zero.

Dhar et al. (2012) used neem oil biodiesel blends to study performance and emission on SCFS engines. The author concluded that lower biodiesel blends (up to B20) could be used in unmodified CI (compression Ignition) engines without compromising engine performance and emission characteristics.

Chauhan et al. (2012) implemented jatropha biodiesel blends to study performance and emission on SCFS engines. The study results showed that the engine performance with biodiesel of jatropha and its blends was comparable to that of diesel fuel. The oxides of nitrogen from jatropha biodiesel during the whole range of the experiment were higher than diesel fuel.

Mallikappa et al. (2012) used cardanol biofuel blends to study the performance and emission of MCFS engines. The authors found that with higher loading, brake thermal efficiency increases. Emission levels were found to be nominal, up to 20% blending.

Habibullah et al. (2014) used Palm (PB), coconut (CB), and Palm+coconut (PBCB) to study the performance and emission of the SCFS engine. The experimental analysis revealed that the combined blend of palm and coconut oil had superior performance and emission over individual Coconut and Palm biodiesel blends. CO and HC emissions were reduced to a great extent at 13.75–17.97%, compared with diesel fuel operation. PB30 showed 5.15% and 18.83% higher CO and HC emissions, respectively, compared with the values for CB30. Meanwhile, PB15CB15 showed lower CO and HC emissions (2.43% and 9.35%, respectively) than PB30 and slightly higher emissions (2.60% and 7.72%, respectively) than CB30 fuel. At the same time, BSEC values were higher (8.55–9.03%) than PB15. CB15 showed slightly higher BTE (1.12%) than PB30 and slightly lower BP and BTE (0.20% and 0.12%, respectively) than CB30 fuel. PB15CB15 showed a 1.22% higher NO_x emission than PB30 and a 1.20% lower NO_x emission.

Imtenan et al. (2014) used palm-jatropha combined biodiesel blends to study the performance and emissions of the SCFS engine. The study revealed that compared to diesel fuel, the study concluded with reduced carbon monoxide (CO) emissions for PBJB5 and PBJB10 (9.53% and 20.49%). On the contrary, hydrocarbon (HC) emissions for PBJB5 and PBJB10 were reduced by 3.69% and 7.81% compared to diesel fuel.

Palash et al. (2015) included blends of methyl esters of *Aphanamixispolystachya* blends (APME) to study the performance and emissions of turbocharged MCFS engines. The study found that APME5 and APME10 showed an average 0.9% and 1.81% reduction in torque and 0.9% and 2.1% reduction in brake power (BP). The brake-specific fuel consumption increase was 0.87% and 1.78% compared to diesel. In engine emissions, diesel blends of APME gave an average reduction in carbon monoxide (CO) and hydrocarbon (HC) emissions compared to pure diesel. However, APME blends emitted higher levels of nitrous oxide compared to diesel. It was suggested that APME5 and APME10 could be used as diesel fuel substitutes without any engine modifications.

Perumal and Ilangkumaran (2017) used methyl esters of *Pongamia pinnata* blends in an SFCS engine to study the performance and emissions of the engine. The study revealed that using PME as fuel reduces carbon monoxide to 8.2% compared to diesel; at the same time, HC was reduced by 8.9%, and a considerable reduction in nitrogen oxides. There was an increase in BSEC of 4.2%, and the thermal efficiency was reduced by 2.4%.

Patel and Sankhavera (2017) reviewed the application of *Pongamia pinnata* biodiesel blends and their applications in diesel engines. The review concluded that both efficiency and emissions of the diesel engine are comparable with 20% blending.

Damanik et al. (2018) reviewed different sources of biodiesel application in diesel engines. The review concluded that most biodiesel blends significantly decrease carbon monoxide and total unburned hydrocarbon emissions. There is also a decrease in carbon monoxide, nitrogen oxide, and total unburned hydrocarbon emissions. At the same time, the engine performance increases for diesel engines fueled with biodiesels blended with nano-additives. The development of automotive technologies, such as exhaust gas recirculation systems and low-temperature combustion technology, also improves the thermal efficiency of diesel engines and reduces nitrogen oxide.

Leksono et al. (2018) studied *Pongamia pinnata*'s sustainability as a biodiesel source. The study suggests that the leguminous tree *Pongamia* could be utilized to produce biofuel while restoring degraded land. Its height is 15–20 m, and it can grow in various environmental conditions. Its seeds can generate up to 40% crude oil by weight. It can help restore degraded land and improve soil properties.

2.2 Emulsifying agents with biodiesel

Singh et al. (2010) used Aqueous ethanol and 1-butanol with crude and virgin coconut oil (CCO and VCO) biodiesel blends in an SFCS engine to study the performance and emissions of the engine. The study revealed that SO₂ (Sulfur dioxide) emission for hybrid fuels is reduced by as much as 54% for CCO-based hybrid fuels and 53% for VCO-based hybrid fuels compared to diesel. The viscosity of the hybrid fuels can be decreased and brought merely to the viscosity of diesel using micro emulsification techniques.

Subbaiah and Gopal (2011) included rice bran (RB) oil and ethanol blends in the SFCS engine. The authors' study showed that the maximum brake thermal efficiency was obtained with 2.5% ethanol blended with RB and 6.98% and 3.93% higher than diesel fuel and biodiesel, respectively, at full engine load. A minimum BSFC of 0.339 was observed among the ethanol blends with 2.5% ethanol. The ethanol blending reduced the exhaust gas temperature. The lowest carbon monoxide, hydrocarbons, and unused oxygen emissions were recorded with a 2.5% ethanol blend. The smoke of the biodiesel was reduced by 20% when blended with 7.5% of ethanol. The maximum reduction of smoke was 27.47%, with 2.5% ethanol blending.

Prakash et al. (2013) included bi-oil with jatropha methyl esters(JME) biodiesel blends in an SFCS engine to study the performance and emissions of the engine. The study concluded a significant reduction in nitrous oxide emissions by 2.5% with 5% Bio-oil and 15% JME blended with diesel. The smoke opacity decreased by 25%, 26.7%, 22.1%, and 18.2% for JME and its emulsions compared to diesel at full load.

Palash et al. (2014) introduced di-phenylenediamine with jatropha biodiesel blends in an SFCS engine to study the performance and emissions of the engine. The observation revealed that By the addition of 0.15% (m) DPPD additive in JB5, JB10, JB15, and JB20,

the reduction in NO_x emissions were 8.03%, 3.503%, 13.65%, and 16.54%, respectively, compared to biodiesel blends without the additive under the full-throttle condition.

Shahir et al. (2014) assessed the feasibility of the diesel–biodiesel–ethanol/bioethanol blend as existing CI engine fuel. The results concluded that the use of diesel–biodiesel–ethanol/bioethanol blend could minimise the use of diesel fuel by approximately 25–30%.

Bora et al. (2015) studied the atomisation characteristics using oleyal alcohol (OA) and ethylene glycol butyl ether with fatty acid methyl esters. The study concluded that droplets increased from 1.88×10^{18} to 6.60×10^{22} . The average length of the surface-active agent decreased from 8.8 to 0.26 nm. The introduction of OA and FAME (fatty acid methyl Ester) also increased the gross calorific value (GCV) (from 38.91 to 40.21 MJ/kg).

Rajesh Kumar and Saravanan (2016) introduced Isobutanol (B), and Iso-pentanol (P) blends in an SCFS engine to study the engine's performance characteristics. The study revealed that B40 gives a longer ignition delay, higher peak pressure, and higher premixed heat release rate than P40. B40 has a better effect on the NO_x-smoke trade-off when compared to P40. At retarded injection timing (21° crank angle before Top dead centre) and 30% exhaust gas recirculation, B40 presented simultaneous reduction of NO_x (↓41.7%) and smoke (↓90.8%) emissions with diesel-like performance. In contrast, P40 simultaneously reduced NO_x (↓39.3%) and smoke (↓15%) emissions with a slight drop in performance.

Perumal and Ilangkumaran (2018) used water with Pongamia pinnata methyl ester as blends in the SCFS engine to study engine performance parameters. The result revealed a 9% increase in BSFC and a 5% decrease in BTE (Brake thermal efficiency) with a reduction of around 32% in NO_x emission. The smoke was reduced to 7.4%. CO and HC emissions have been reduced to a marginal value of 2.3% and 1%, respectively.

Sidhu et al. (2018) introduced glycerine with biodiesel and diesel blends to study the SCFS engine's performance parameters and emissions. Results showed that with the increase in glycerine concentration, brake-specific fuel consumption and brake-thermal efficiency increased. Regarding emissions, it was seen that carbon monoxide and unburnt

hydrocarbon increased, and reductions in exhaust gas temperature and nitrogen oxides were observed.

Ahmad et al. (2018) introduced non-surfactant water (NW) prepared from tap water, rainwater, and seawater to blend with diesel in an SCFS engine. The result showed that NW diesel made from tap water helps the engine reduce NO_x by 32%. Rainwater reduced it by 29% and seawater by 19%. Also, all NWs show significantly improved engine performance compared to diesel fuel.

Arunprasad et al. (2020) used a Jatropha and Pongamia biodiesel mixture. The supplements were used with 25, 50, 75, and 100% blendings with diesel. The findings of the engine study showed that The reduction of HC (hydrocarbon), CO (carbon monoxide), smoke emissions, and an increase of NO_x (nitrogen oxides) for different loads was observed and compared with diesel at all loads.

2.3 Application of Regression and ANOVA to develop a prediction model for engine performance

Al-Iwayzy and Yusaf (2017) used blends of microalgae biodiesel from *Chlorella Protothecoides* (MCP-B) to estimate diesel engine performance. The analysis of variance (ANOVA) was performed to evaluate the significance of the means of the parameters. The results showed that MCP-B100 produces fewer emissions compared to petroleum diesel. Statistically significant differences were found in engine brake power, torque, BSFC, exhaust gas temperature, CO, O₂, and NO_x when MCP-B100 and its mixtures were used compared to PD. The MCP-B100 showed a 7, 4.9, 6.1, 28, 4.2, and 7.4% reduction in stopping power, torque, exhaust gas temperature, CO, CO₂, and NO_x, respectively.

Rahim and Rasul (2019) used diesel-tomato seed oil biodiesel (TSOB) blends to determine the performance and emissions of an SCFS diesel engine. The regression models showed that the torque decreases with increasing the engine speed and biodiesel percentage. These results also show that the highest and the lowest SFC are related to B0 and B20, respectively.

Pandian et al. (2011) used regression and ANOVA analysis to predict the performance and emissions of an SCFS diesel engine powered with Pongamia biodiesel blends. The results showed that the opacity of BSEC, CO, HC, and smoke was lower. BTE and NO_x were

higher at a 2.5 mm nozzle tip protrusion, 225 bar injection pressure, and 30 ° BTDC Injection. The injection system parameters were optimized using the response surface methodology for better performance and lower NO emissions. An injection pressure of 225 bar, an injection timing of 21° BTDC, and a 2.5 mm nozzle tip protrusion were optimal values for diesel fuel operation blended with Pongamia biodiesel in the diesel engine. 7.5 kW test at 1500 rpm.

Amarnath and Prabhakaran (2012) used the genetic algorithm optimisation technique to evaluate the optimised parameters, namely load, compression ratio, injection pressure, and blend. The author used the Karanja methyl esters blend to conduct SCFS engine experiments. Concerning maximum efficiency and minimum emissions, the optimised load, compression ratio, injection pressure, and blend values were 6 kg, 18, 247 bar, and 95%, respectively.

Pohit and Misra (2013) used grey relational analysis and the Taguchi method to optimise studies on an IC engine's performance and emissions. A 50% mixture was found to be the most suitable for use in a diesel engine without significantly affecting engine performance and emissions characteristics. Sivaramakrishnan Kaliamoorthy, and Ravikumar Paramasivam

Kaliamoorthy and Paramasivam (2013) used Taguchi's approach analysis to optimise the Karanja biodiesels engine's performance. The study concluded that BTE, BSFC, and diesel engine emissions depend upon biodiesel blend, compression ratio (CR), nozzle pressure, and injection timing (IT). The results showed that a diesel engine operating at a CR –17.7, pressure 230 bar, IT of 27° BTDC, biodiesel – diesel blends B20, and brake power –3.64 kW achieves the optimum engine performance. The findings of our confirmatory test well support the results.

Ahamad et al. (2018) used the grey Taguchi method to predict the performance parameters. As per the thermal performance evaluation, it is observed that the engine's operating conditions with 30% polanga biodiesel blend at 220 bar injection pressure are similar to the operating conditions with diesel. Taguchi method has been adapted to obtain a rich design matrix for optimization of parameters. The engine's input parameters are optimized with BTE, UHC, NO_x, and smoke multi-response characteristics. Multiple single-to-noise ratios (MSNR) are employed to analyze the performance characteristics

from the actual value. In the study, the optimal values of BTE, UHC, NO_x, and smoke emissions obtained are 32.59%, 20.3 ppm volume, 551 ppm volume, and 94.2%, respectively, at 30% polanga biodiesel blend with 15°bTDC fuel injection timing and 200 bar injection pressure.

Rao and Rao (2017) used grey relation analysis to optimise the parameters obtained from mahua methyl esters (MME) biodiesel results in the SCFS engine. It was observed that the experimental results almost coincided with the validation results. The optimal combination observed was 20 kg of load and MME + 3% Methanol as the fuel.

Ahamad et al. (2018) used polanga biodiesel blends to study the performance of an SCFS engine. Further, the Taguchi method was optimised to obtain the best parameters. The study concluded that the optimal values of BTE, UHC, NO_x, and smoke emissions obtained are 32.59%, 20.3 ppm volume, 551 ppm volume, and 94.2%, respectively, at 30% polanga biodiesel blend with 15°bTDC fuel injection timing and 200 bar injection pressure.

Thodda et al. (2020) used acetylene and diesel as fuel in dual mode to test the engine's performance. A multi-objective optimisation was conducted using the RSM To evaluate optimized parameters. The results showed a high flow rate of acetylene injection of 6 lpm, higher IP of 240 bar, CR of 18, and IT of 23°CA BTDC arrived as the optimum operating conditions.

Simsek and Uslu (2020) studied the effects of mixing three sources of biodiesel (canola, waste vegetable oil, and safflower) on the performance and emissions of the SCFS engine. Optimisation studies using response surface methodology were also conducted to find optimum BTE, BSFC, and emissions. The optimum BTE, BSFC, NO_x, CO, HC, and smoke responses were 19.782%, 385.790g/kWh, 436.951ppm, 0.0272%, 33.639 ppm, and 0.167%, respectively.

Aneeque et al. (2021) studied the impact of additives N-octanol and N-butanol with Calophyllum inophyllum biodiesel on the engine's performance and emissions. The response surface methodology (RSM) optimisation revealed that the optimised thermal efficiency and emission were obtained at full and minimum loads, respectively. N-octanol addition hindered emission at all loads, while N-butanol reduced it at higher loads.

2.4 Application of ANN prediction modelling for engine performance

Ghobadian et al. (2009) studied the implementation of artificial neural network (ANN) modelling of a diesel engine using waste cooking biodiesel fuel to predict the engine's brake power, torque, specific fuel consumption, and exhaust emissions. The experimental results revealed that blends of the waste vegetable oil methyl ester with diesel fuel improve engine performance and emission characteristics. An ANN model was developed based on the engine's standard back-propagation algorithm. A multi-layer perception network (MLP) was used for non-linear mapping between the input and output parameters. Different activation functions and several rules were used to assess the percentage error between the desired and the predicted values. It was observed that the ANN model could predict the engine performance and exhaust emissions quite well with correlation coefficient (R) 0.9487, 0.999, 0.929, and 0.999 for the engine torque, SFC, CO, and HC emissions, respectively. The prediction MSE (Mean Square Error) error was between the desired outputs as measured values, and the simulated values were obtained as 0.0004 by the model.

Saritas et al. (2010) used an artificial neural network to predict performance using diesel fuel, biodiesel, B20, and bioethanol–diesel fuel having different percentages (5%, 10%, and 15%). Biodiesel was mixed to be used in a developed artificial neural network. Mixtures were also controlled for their fuel properties, and motor experiments were performed to collect the reference values. Power, moment, hourly fuel consumption, and specific fuel consumption were estimated using the artificial neural network developed using reference values. Estimated values and experiment results are compared. As a result, from the performed statistical analyses, the realised artificial intelligence model is an appropriate model to estimate the engine's performance used in the experiments., the reliability value was found to be 99.94% ($p = 0.9994$ and $P > 0.05$) after conducting statistical analysis.

Kannan et al. (2013) predicted the Effect of injection pressure and injection timing on a diesel engine's performance, emission, and combustion characteristics fuelled with waste cooking palm oil-based biodiesel using the artificial neural network (ANN) model. Experiments were carried out in a single-cylinder, four-stroke direct injection diesel engine at a constant speed of 1500 rpm and full load (100%) conditions to acquire data for training and testing in the proposed ANN. The experimental results showed that

waste-cooking palm oil methyl ester improved engine performance, emission, and combustion characteristics at 280 bar and 25.5o BTDC injection pressure. An ANN model was developed using the data acquired from the experiments. Training of ANN was performed based on a back-propagation learning algorithm. The multi-layer perceptron (MLP) network was used for mapping non-linear input and output parameters. Among the various networks tested, the network with two hidden layers and 11 neurons gave a better correlation coefficient for engine performance, emission, and combustion characteristics. The ANN model was validated with the test data not used for training and was very well correlated.

Cirak and Demirtas (2014) Implemented an artificial neural network (ANN) model to predict the torque of a diesel engine. Experiments on the performance of a diesel engine using biodiesel produced from canola and soybean oils through transesterification were carried out to acquire data for training and testing of the proposed ANN. An MCFS test engine was fuelled with biodiesel and euro diesel mixture fuels with various percentages of biodiesel % amounting to half the CB with SB and operated at different loads engine speeds, coolant temperatures, biofuel mixtures, exhaust temperature, etc. Levenberg Marquardt algorithms for the engine were developed using experimental data for training as a non-linear system has been accepted. The performance of the ANN was validated by comparing the prediction dataset with the experimental results. It was observed that the ANN model could predict the engine performance quite well with a correlation coefficient of R 0.98 for the engine torque, respectively. The prediction MSE (Mean Square Error) error was between the desired outputs as measured values, and the simulated values were obtained as 0.0002 by the model.

Shukri et al. (2015) studied engine performance using a mixture of palm oil methyl ester blends with diesel oil as biodiesel in a diesel engine and optimised engine performance using artificial neural network (ANN) modelling. To acquire data for training and testing of the proposed ANN, a four-cylinder, four-stroke diesel engine was fuelled with different palm oil methyl ester blends as biodiesel and operated at different engine loads. The properties of biodiesel produced from waste vegetable oil were measured based on ASTM standards. The experimental results revealed that palm oil methyl ester blended with diesel fuel improved engine performance. An ANN model was developed based on the Levenberg-Marquardt algorithm for the engine. Logistic activation was used for mapping

between the input and output parameters. It was observed that the ANN model could predict the engine performance quite well with correlation coefficients (R) of 0.996684, 0.999, 0.98964, and 0.998923 for the in-cylinder pressure, heat release, thermal efficiency, and volume, respectively.

Rao et al. (2017) investigated the performance and emission characteristics of SCFS indirect diesel injection (IDI) engine fueled with Rice Bran Methyl Ester (RBME) with Isopropanol additive. The investigation is done through experimental data analysis and artificial neural network (ANN) modelling. The study used IDI engine experimental data to evaluate nine engine performance and emission parameters, including exhaust gas temperature (EGT), Brake Specific Fuel Consumption (BSFC), Brake Thermal Efficiency (B.The), and various emissions like Hydrocarbons (HC), Carbon monoxide (CO), Carbon dioxide (CO₂), Oxygen (O₂), Nitrogen oxides (NO_x) and smoke. The standard backpropagation algorithm was the optimum choice for the ANN modeling for training the model. A multi-layer perception (MLP) network was used for non-linear mapping between the input and output parameters. It was found that ANN was able to predict the engine performance and exhaust emissions with a correlation coefficient of 0.995, 0.980, 0.999, 0.985, 0.999, 0.999, 0.980, 0.999, and 0.999 for EGT, BSFC, BTE, UHC, O₂, CO₂, CO, NO_x, smoke, respectively.

Karami et al. (2019) used diesel-tomato seed biodiesel (TSOB) blends to determine the performance and emissions of an SCFS diesel engine. The ANN model can predict the engine performance parameters and emissions without running costly and time-consuming experiments with the histogram error of 0.004 and R = 0.96.

Sajjadi et al. (2016) reviewed the application of ANN for studying engine behaviour in implementing biodiesel in diesel engines. The study concluded that using ANN with trained, tested, and validated data was introduced to determine a diesel engine's performance and emission characteristics fueled with biodiesel-based fuel. In general, the ANN model could supply a relatively high determination coefficient compared to predicted results and experimental data, showing that the ANN model could have an excellent ability to predict engine behaviours with an accuracy higher than 95%.

Simsek et al. (2022) used waste animal fat oil and predicted the engine response using ANN. The developed ANN model could predict engine responses with mean absolute

percentage error (MAPE) in the range of 3.787e10.730%. MAPE values for RSM were obtained between 2.004 and 11.461%.

2.5 Application of biodiesel in the field of mining

Tiffany (2016) studied the importance of biodiesel for underground mines. She concluded that using exhaust filters for Particulate matter (PM)-control will result in ambient PM reductions exceeding 65%. Mine operators would need to use straight biodiesel with catalytic converters to get comparable reductions. Biodiesel will need to fall below \$2.00/gal to be competitive with filters for coal mines and below \$1.25/gal for metal mines. However, biodiesel has advantages that filters do not. Using biodiesel in mines would be easy to implement and would not require miner training. There are no new maintenance procedures required.

Debia et al. (2017) compared exposure levels within and between the mines as well. They studied the various ways of assessing Diesel Exhaust (DE) exposures, such as respirable combustible dust (RCD), elemental carbon (EC), and total carbon (TC); DE exposures in employees at two underground gold mines were assessed. Measurements were made of the ambient air and the personal breathing zone (PBZ). The respirable percentage RCD, EC, and TC, and the worker's breathing zone are all measured concurrently throughout a whole shift (ECR and TCR). In addition to the ambient measurements of ECR, TCR, and RCD, a submicron aerosol fraction of EC and TC (less than 1 μm) was also detected (EC1 and TC1). The average ambient readings for RCD, ECR, and TCR are 240 mg/m^3 , 150 mg/m^3 , and 210 mg/m^3 , respectively. The average PBZ results in TCR, ECR, and RCD were 150 mg/m^3 , 84 mg/m^3 , and 190 mg/m^3 , respectively. ECR and EC1 exhibit a very strong association, with a calculated Pearson correlation coefficient between the two log-transformed concentrations of 0.99 ($p < 0.01$), indicating a significant link. Between ECR and EC1, there were no reported differences. The load haul-dump (LHD), jumbo drill operators, and traditional miners have the highest exposures. Truck and LHD operators have significant exposure variations between mines ($p < 0.01$). The average TCR/ECR ratio for PBZ and ambient results is 1.6 and 1.3, respectively.

Lutz et al. (2017) conducted a diesel and biodiesel exposure study in underground mines. Using a load-haul-dump vehicle, personal exposure monitoring was performed in a non-operational, hard rock underground mine. Eight-hour time-weighted average (TWA8)

exposure concentrations of ultra-low sulfur diesel and 75% biodiesel/25% diesel blend (B75) fuels were compared. The use of a blend of 75% was linked to relative percent reductions in median respirable (r) diesel particulate matter (DPM) and nitrogen dioxide of 22 and 28%, respectively, and increases in median total DPM and nitric oxide TWA 8 exposure doses of 25 and 23%, respectively, when compared to diesel. Diesel was linked to a slightly lower mean surface area concentration and higher total geometric mean mass concentration. The blend of 75% might lessen DPM exposures.

Tiffany (2016) studied the importance of biodiesel for underground mines. She concluded that the use of exhaust filters for particulate matter (PM) control will result in ambient PM reductions exceeding 65%. Mine operators would need to use straight biodiesel with catalytic converters to get comparable reductions. Biodiesel costs need to fall below \$2.00/gal to be competitive with filters for coal mines and below \$1.25/gal for metal mines. However, biodiesel has advantages, such as applying biodiesel in mines would be easy to implement. It would not require much training for the workers.

2.6 Research gap

Alternative fuel is most necessary for the replacement/ accomplishment of depleting mineral fuel for future sustainability. It is needed to compensate for the economy of using vegetable oils. The literature gaps identified include the need for alternative fuel for demanding future energy generation in mining industry, sustainability, and cost optimization.

The best suggestion would be to use a combination of two or more sources of alternative fuels. Hence, waste cooking oil is used as an additional source to compensate for the cost of yielding raw Pongamia oil. The literature review reveals that studies on Pongamia pinnata and other such oils qualify to a larger extent. The governing authorities regularised it under the Indian biofuel policy 2015, stating that a blend of 20% is to be implemented with diesel for future sustainability and optimal performance.

The mine environment plays a significant role in enhancing the health condition of the workers. Biodiesel implementation can undoubtedly contribute to regulating engine emissions compared to diesel, especially carbon monoxide. Biodiesel can be sustainable with the addition of alcohol and other emulsifying agents. Ethanol, as one such additive,

can be used to attain the sustainability of biofuels. Ethanol and acetone are the two agents used in this study to evaluate engine performance and emission characteristics.

CHAPTER 3

OBJECTIVES, METHODOLOGY, EXPERIMENTATION AND ALTERNATIVE FUEL PROPERTIES

3.1 Introduction

This chapter describes the details of the experimental setup and the instruments and standards involved. Also, the properties are listed down.

3.2 Objectives

Objectives of the proposed research work are:

- 1 To prepare blended alternative fuels using Pongamia pinnata and waste cooking oil (WCO) in the form of methyl esters, a combination mixture of Pongamia pinnata and WCO methyl esters (50:50 by volume), raw form of Pongamia pinnata and emulsification using acetone and ethanol.
- 2 To determine and study the physico-thermal properties, namely density, kinematic viscosity, and calorific value of diesel and the blends of prepared alternative fuels.
- 3 To study the performance and emissions of a single-cylinder four-stroke diesel engine using diesel and blended alternative fuels.
- 4 To determine the relationship between the physico-thermal properties of the prepared alternative fuels with the performance and emissions of the four-stroke diesel engine using statistical and artificial neural network techniques.
- 5 To study the Effect of the blends of RPO, MPO, MWO, and MPWO on emissions of the mining equipment. as per the Indian biofuel regulation 2010.

3.3 Methodology

1. The flow chart of the research methodology is shown in figure 3.1.

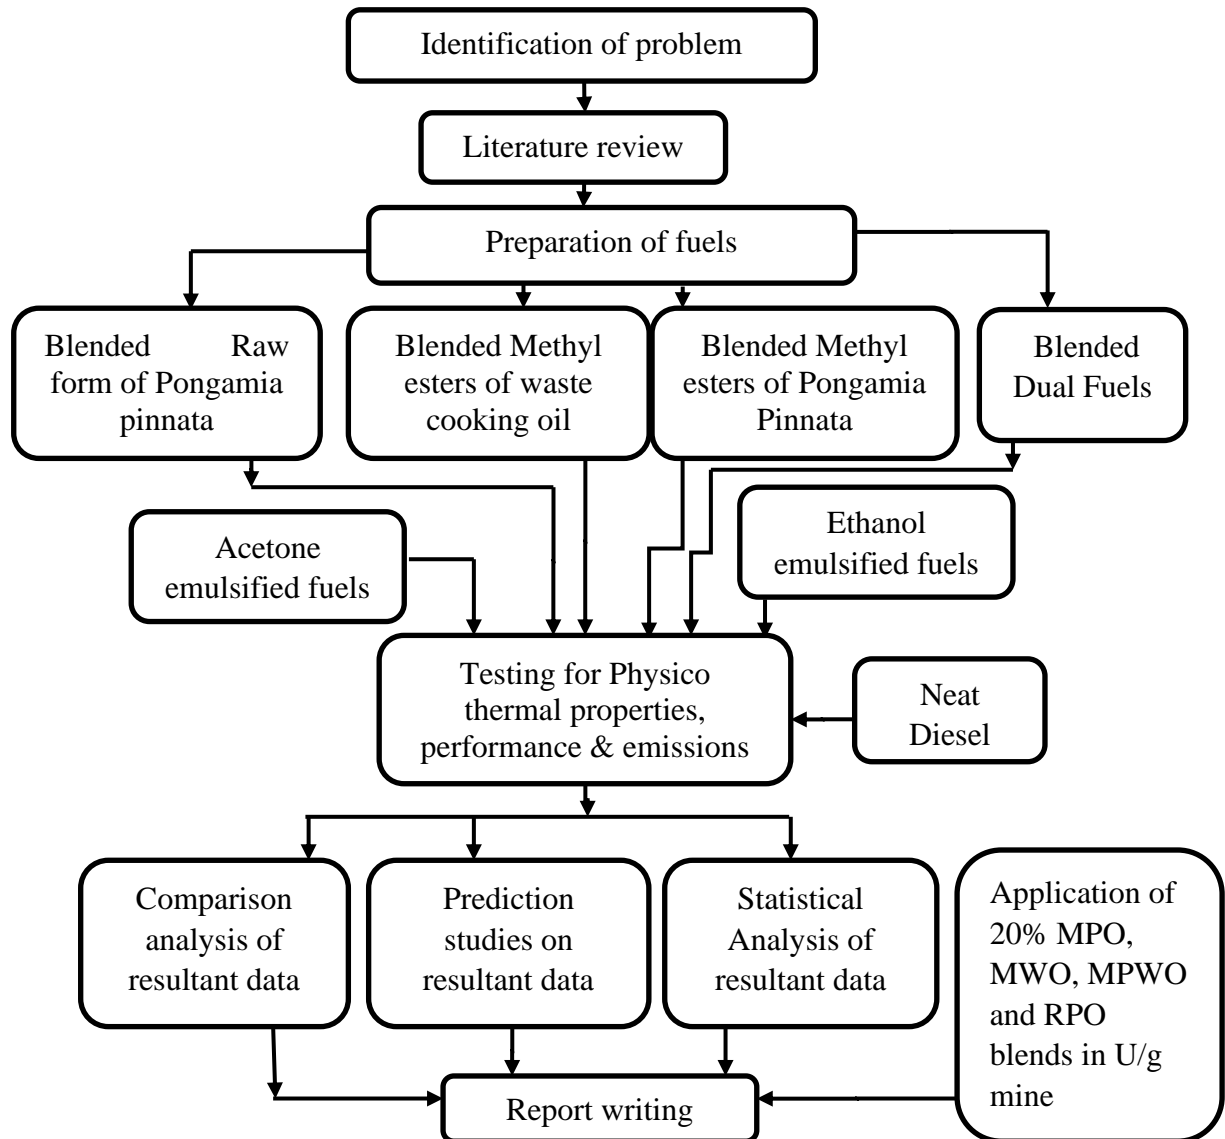

Figure 3.1 Flow chart of the research methodology

2. Carried out a detailed literature review; on different kinds of alternative fuels, including their preparation, usage, performance prediction, and emission from diesel engines.
3. Prepared alternative fuels using raw Pongamia pinnata oil, methyl esters of WCO (Ehsan and Chowdhury 2015), and Pongamia pinnata oil (Babu et al. 2009).

Alternative fuels are prepared as described below.

- a) Methyl esters of Pongamia pinnata (MPO) and waste cooking oil (MWO) in blended ranges from 5% to 30% with an increment of 5% by volume with diesel.
- b) A mixture of MPO and MWO (50%:50%, by volume) MPWO is prepared; in blends ranging from 5% - 30% with an increment of 5% by volume.

- c) Raw Pongamia pinnata oil (RPO); in blends ranging from 5% - 30% with an increment of 5% by volume with diesel.
 - d) Similarly, Adding 10% by volume of ethanol by reducing the quantity of diesel; for diesel and the samples discussed in Points a, b, and c. Respectively, the samples are labeled as DE, RPE, MPE, MWE, and MPWE.
 - e) The subjection of the fuels listed in points a, b, and c, to further addition using acetone by a '10% by volume by reducing the quantity of diesel; for diesel and the samples discussed in Points a, b, and c. the samples are labeled as DA, RPA, MPA, MWA, and MPWA, respectively. The chart for specimen preparation is shown in figures 3.2 to 3.6.
4. Determining physico-thermal properties such as density, kinematic viscosity, and calorific value for the prepared alternative fuels. The standards used in the estimation of properties are listed in Table 3.1.
 5. Performance and emission studies are conducted on a single-cylinder 4-stroke water-cooled direct injection diesel engine using the prepared alternative fuels described under point 2. The specifications of the engine are shown in Table 3.2. The schematic diagram for the test set-up is shown in Figure 3.7, and the pictorial view of the engine is shown in Figure 3.8. The procedure for engine testing is as follows:
 - a) The condition chosen for the engine test includes maintaining a constant engine speed of 1500 rpm for each varied engine load from 0 % to 100% in increments of 25%. The experiment is carried out for all prepared alternative fuel samples.

Figure 3.2 Preparation of ethanol and acetone added to diesel sample

Figure 3.3 Preparation of RPO, ethanol, and acetone-added RPO biodiesel blends

b) The time for 10 Cc fuel consumption and the emission parameters, namely, carbon monoxide (CO), carbon dioxide (CO₂), unburnt hydrocarbon (UHC), and oxides of nitrogen (NOX), is recorded at each loading condition for each blend. AVL 444 exhaust gas analyser is used. The specifications of the analyser are listed in Table 3.3.

6. Evaluate the effects of blending and loading each alternative fuel blend on the engine's performance and emissions.
7. Carry out a regression analysis for the results of multivariate data to identify and understand the relationships between the fuel properties, loads, and blends with the performance and emissions of the engine using multivariate regression analysis and ANOVA.
 - a) The output variables chosen include BTE, BSEC, CO, CO₂, UHC, and NOX. Engine load, fuel blends, the mass of fuel consumed, and the properties, namely density (D), kinematic viscosity (KV), and calorific value (CV), are considered input parameters.
 - b) The significant parameters (P-Value) and their contributions (F- Value) are tested under ANOVA analysis.
 - c) The regression equation and performance of the model (R-Squared) are tested under regression analysis
 - d) Minitab V19 is used to carry out both ANOVA and Regression analysis.
8. Carry out prediction studies on the performance and emission of the engine using the ANN technique.
 - a) The output and input parameters are chosen as in Point 6 (a).
 - b) The analysis is performed using MatLab 2019 a. NNTOOL command to start the analysis. The input and output variables are fed to the MatLab workspace.
 - c) A network with two hidden layers is created for the hidden layer for the input and the output layer. A feed-forward back-propagation network is used to develop the model.

- d) TRAINLM and LEARNGDM are used as the training and learning algorithm. The transfer function is TRANSIG.
- e) The number of neurons varies from 4 to 12 in increments of 1. To observe and arrive at the optimised model. The root Mean square error (RMSE) is computed, and the optimised model is then suggested based on the least RMSE.
8. An evaluation study on the implementation of base biodiesel blends as per the Indian biofuel policy on the equipment used in an underground mine was carried out on a tipper of the Hutti Gold Mine Ltd., Karnataka. Emissions, namely CO, NO (nitrous oxide), NO₂ (nitrogen dioxide), and NO_x (oxides of nitrogen).
9. Reporting and concluding the effects of blending each alternative fuel blend on the engine's emissions and variations measure with reference to diesel in a mining tipper. The specifications of the mine tipper are shown in Table 3.4

Table 3.4 Specifications of the mine tipper

Max. Torque	490 Nm @ 1400 r/min
No. Of Cylinders	Six (Inline)
Engine Capacity	5675 CC

3.4 Properties of the prepared alternative fuels

A preliminary investigation of the characteristics of prepared fuels is assessed. The study aims to verify that fuel standards are being met and is very beneficial in determining the best combination that might be added to diesel fuel. Three major properties, namely Density, Kinematic viscosity, and calorific value, are studied. The average deviation concerning diesel of all prepared samples is estimated. The average deviations concerning diesel are tabulated in Table 3.5. A comparison plot is shown for ethanol and acetone additions in bar graphs. The effect of ethanol and acetone additions are shown as scatter plots for each sample. A comparison study was carried out to determine the effects of mixing two methyl esters and properties deviations with reference to MPO.

Table 3.5 Average deviation of the physico-thermal properties of prepared samples.

Sample	Deviation (in %)		
	Density	Kinematic viscosity	Calorific value
DA	0.73	0.25	-0.30
DE	0.97	0.51	-2.20
MPO	-1.54	-8.59	1.95
MPA	-0.77	-7.19	1.48
MPE	-1.27	-5.58	1.22
MWO	-1.21	-6.35	0.59
MWA	-0.71	-5.88	0.77
MWE	-0.63	-5.33	-0.54
MPWO	-1.41	-9.35	1.41
MPWA	-0.67	-7.91	0.63
MPWE	-0.71	-7.06	-0.80
RPO	-1.66	-13.24	1.81
RPA	-1.39	-10.36	1.30
RPE	-1.11	-6.77	0.60

3.4.1 Density

Density is a vital physical fuel property that signifies how much fuel an engine uses and how much power it can make. It affects the working of the engine and how much pollution it puts out (Ramírez Verduzco 2013). If one type of fuel is much denser, more mass goes into the combustion chamber for the same amount of space. Generally, the fuel density increases with increased biodiesel blending due to the biodiesel's lower carbon and hydrogen content (Hoekman and Robbins 2012). Ethanol and acetone addition to the base biodiesel blends improves the quality of base biodiesel blends (Jimenez and Svolj 2010). The lower the density of the fuel higher would be the fuel quality.

Figure 3.9 shows the Effect of ethanol and acetone on diesel. However, the improvements in diesel density due to ethanol and acetone additions are found to be 0.73% and 0.97%, respectively. Figure 3.10 shows the Effect of mixing two methyl esters. Adding MPO to MWO, improvements in density are found for MPO; MPWO shows a 0.11% improvement in density. Figure 3.11 to 3.14 shows the Effect of ethanol addition and acetone addition on RPO, MPO, MWO, and MPWO. Adding ethanol and acetone has improved the density of the base biodiesel samples. However, the most significant

deviation is found with RPO with a variation of 1.66%. Hence, RPO can be considered a poor source as far as density is concerned.

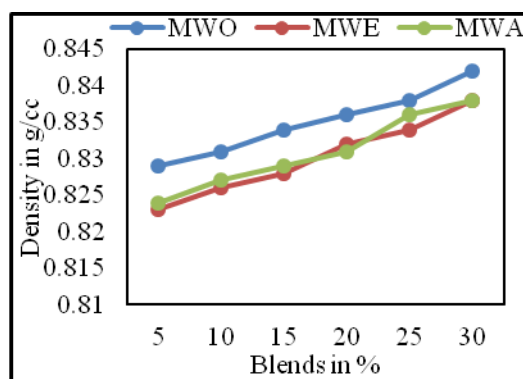

Figure 3.12 Effect of ethanol and acetone blending on the density of MWO blends

Figure 3.13 Effect of ethanol and acetone blending on the density of MPWO blends

Figure 3.14 Effect of ethanol and acetone blending on the density of RPO blends

3.4.2 Kinematic viscosity (KV)

An essential characteristic of fuel is kinematic viscosity, which directly affects fuel atomization's effectiveness and the spray's fuel droplet size. A lower kinematic viscosity improves the fuel's ability to spray better. Diesel's properties may deteriorate by adding biodiesel blends (Hoekman and Robbins 2012). This may be due to Influencing factors such as chain length, position, number, nature of double bonds, and oxygenated moieties (Knothe and Steidley 2005). Ethanol and acetone additions improve diesel's kinematic viscosity (Wu-gao et al. 2005) and base biodiesel blends (Mahalingam et al. 2018). This is because of the lower kinematic viscosity of ethanol on the biodiesel blends. However, ethanol shows better improvement in the improvement of kinematic viscosity compared to acetone.

Figure 3.15 shows the Effect of adding acetone and ethanol on diesel fuel's kinematic viscosity. Both ethanol and acetone decrease the kinematic viscosity of diesel. The measured deviation of DE and DA with reference diesel is 0.25% and 0.51%, respectively.

Fig 3.16 depicts the Effect of combining the two methyl esters, MPO and MWO; adding MWO to MPO tends to reduce the kinematic viscosity of the MPO blend sample. This is because of the lower viscosity of MWO, which affects the reduction. The improvement achieved by MPWO compared to MPO addition is 2.96%. Figures 3.17 to 3.20 illustrate the significance of ethanol and acetone additions to MPO, MWO, MPWO, and RPO blended samples. Ethanol and acetone show reduced kinematic viscosity. The largest deviations are found with RPO, which is 13.24% higher than diesel. Hence, RPO is considered a poor source regarding kinematic viscosity.

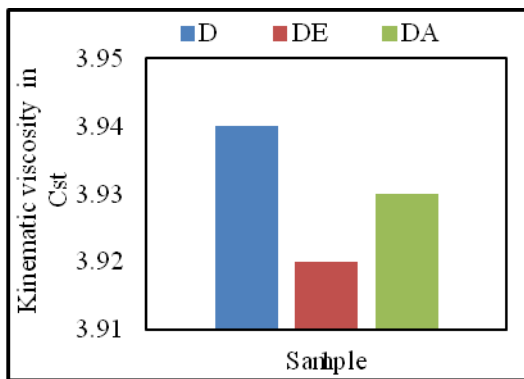

Figure 3.15 Effect of ethanol and acetone blending on the KV of diesel

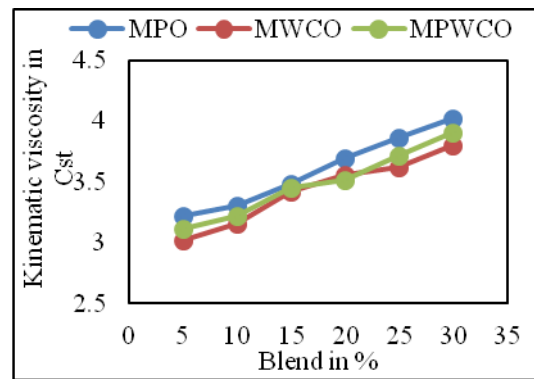

Figure 3.16 Comparison of KV of MPWO with MPO and MWO blends

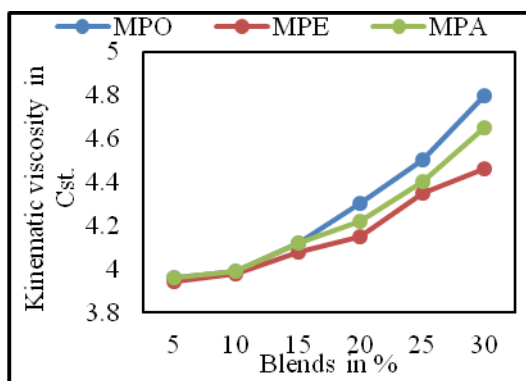

Figure 3.17 Effect of ethanol and acetone blending on the KV of MPO blends

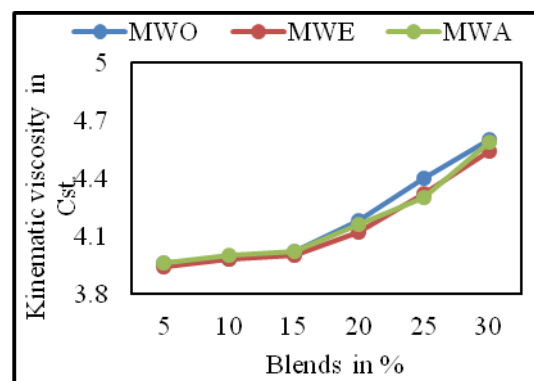

Figure 3.18 Effect of ethanol and acetone blending on the KV of MWO blends

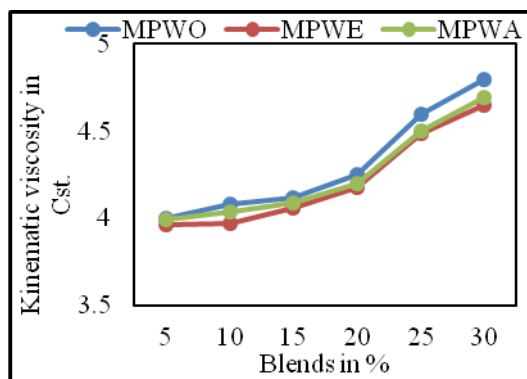

Figure 3.19 Effect of ethanol and acetone blending on the KV of MPWO blends

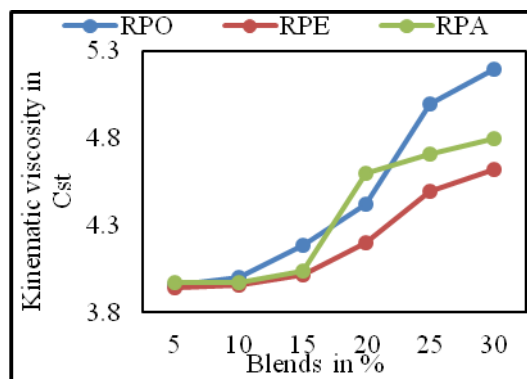

Figure 3.20 Effect of ethanol and acetone blending on the KV of RPO blends

3.4.3 Calorific value (CV)

Figure 3.21 shows how adding acetone and ethanol affects the diesel fuel's calorific value. Both ethanol and acetone can improve the calorific value of diesel. This is due to the

higher calorific values of ethanol and acetone. The improvements in the calorific value of diesel compared to the blend samples are 1.72% and 1.99% for ethanol and acetone additions, respectively.

Fig 3.22 depicts the Effect of combining the two methyl esters, MPO and MWO; adding MWO to MPO tends to increase the calorific value of the MPO blend sample.

The improvements achieved by MPO due to MWO addition are 0.696%.

Figures 3.23 to 3.26 illustrate the effects of ethanol and acetone additions to RPO, MPO, MWO, and MPWO blended samples. The largest deviation with increased calorific value is found with RPO at 1.81%. Hence, RPO is considered the poorest source with reference to diesel.

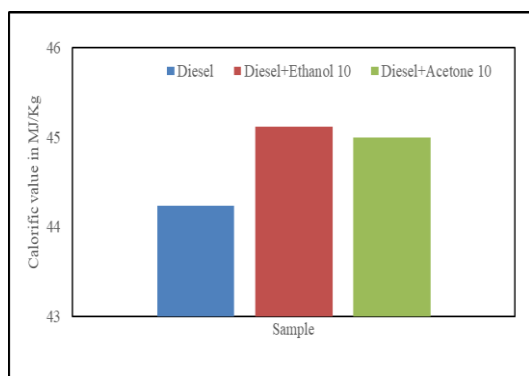

Figure 3.21 Effect of ethanol and acetone blending on the CV of diesel

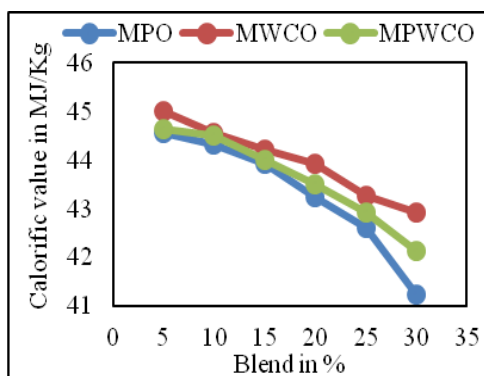

Figure 3.22 Comparison of the CV of MPWO with MPO and MWO blends

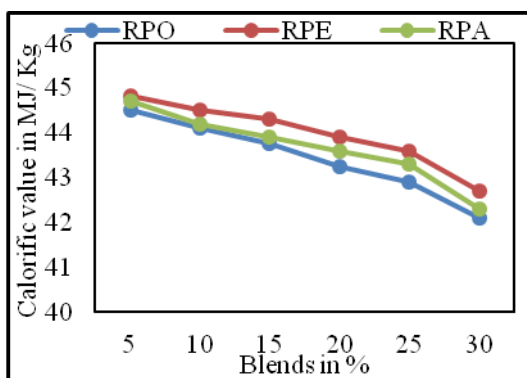

Figure 3.23 Effect of ethanol and acetone blending on the CV of RPO blends

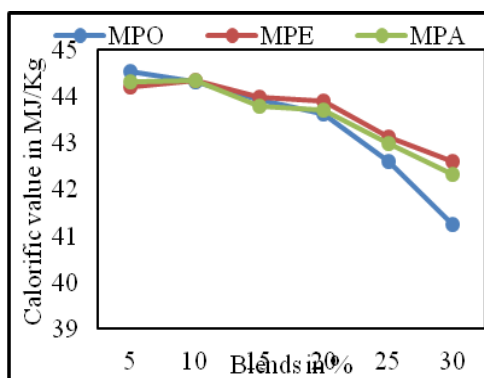

Figure 3.24 Effect of ethanol and acetone blending on the CV of MPO blends

Figure 3.25 Effect of ethanol and acetone blending on the CV of MWO blends

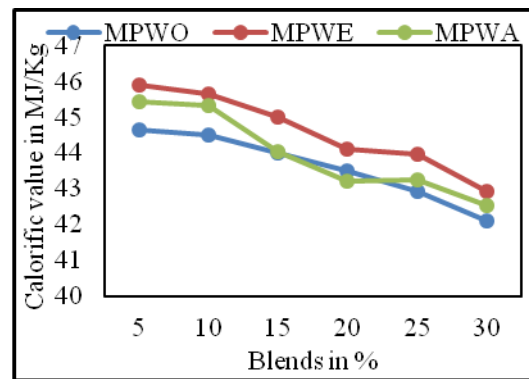

Figure 3.26 Effect of ethanol and acetone blending on the CV of MPWO blends

Calorific value is the number of calories generated when a unit amount of substance is completely oxidised. Calorific value decides the efficiency of an energy source per unit weight. The calorific value of biodiesel blends decreases with an increase in blend percentage (Wakil et al. 2015). The higher the calorific value better would be its fuel characteristics. Ethanol shows improvements in the calorific value of biodiesel blends (Hussan et al. 2013). However, the calorific values of ethanol-added biodiesel blend remain lower than diesel (Sharanappa and Navindgi 2017). With an increase in biodiesel blending, the calorific value decreases. The biodiesel blends' lower calorific values are due to the fuel's higher oxygen content (Kaisan et al. 2020).

CHAPTER 4

EXPERIMENTAL ANALYSIS

This study considers two performance parameters (BTE and BSEC) and four emission parameters (CO, CO₂, UHC and NO_x); the parameters are evaluated and tabulated as shown in Appendix -I. The significance of mixing two methyl esters, namely the *Pongamia pinnata* and waste cooking oil, and the Effect of ethanol and acetone's addition on the engine's efficiency and emissions are studied. The following sections illustrate the significance of the individual parameter. In this study, the estimated parameters are compared as follows.

Case-1: The Effect of constant ethanol and acetone addition individually to the diesel is compared with diesel

Case-2: MPWO is compared with MPO and MWO for each blend.

Case-3: The Effect of ethanol and acetone blended samples on performance and emissions of the engine, i.e., RPE, MPE, MWE, MPWE, and RPA, MPA, MWA

An average deviation of the blends of each prepared biodiesel sample is estimated concerning diesel and is tabulated in Table 4.1.

Table 4.1 Average deviation of prepared samples with diesel.

Sample	Average variation (in %)					
	BTE	BSEC	CO	CO ₂	UHC	NO _x
DA	-2.5974	2.33	17.6471	-12.775	7.69231	-35.345
DE	-3.22	1.99	20.915	-18.062	11.5385	-43.75

RPA	30.4258	-37.69	55.1079	-39.627	48.2294	-163.97
RPE	26.5956	-31.46	57.4706	-49.165	51.1079	-172.68

Mixing two methyl esters has improved both performance and emissions of the poorer source ester (Sanjid et al. 2014; Sridhar et al. 2017).

4.1. Engine performance parameters

4.1.1 Brake thermal efficiency

Figure 4.1 illustrates the Effect of adding acetone and ethanol to diesel on the BTE of the engine. The figure shows a positive Effect of ethanol-diesel (Khalife et al. 2017) than acetone-diesel. It may be because of the higher CV of ethanol than acetone. The variation in BTE of the diesel engine due to 10% ethanol and 10 % acetone additions is found to Be 3.2% and 2.6%, respectively.

Figures 4.2 to 4.7 show the effect of combining two methyl esters, MPO and MWO. Combining MPO with MWO can improve the efficiency of MPO. The average achievement in the efficiency of MPWO as compared to MPO for blending up to 30% by volume is 13.9%.

Figure 4.1 Effect of ethanol and acetone blended diesel on the BTE of engine

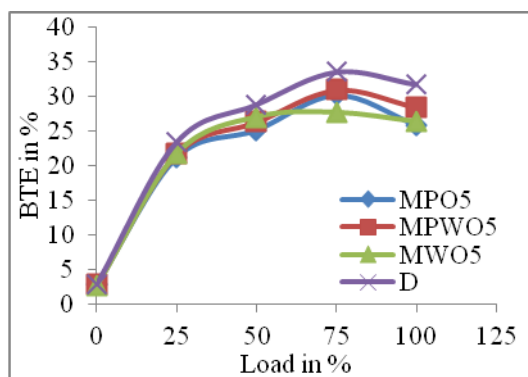

Figure 4.2 Effect of combining MPO and MWO on the BTE of the engine at 5% blending

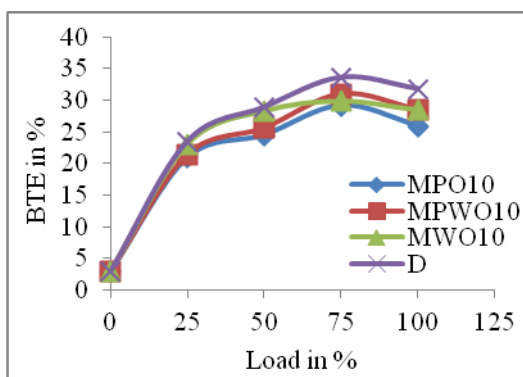

Figure 4.3 Effect of combining MPO and MWO on the BTE of the engine at 10% blending

Figure 4.4 Effect of combining MPO and MWO on the BTE of the engine at 15% blending

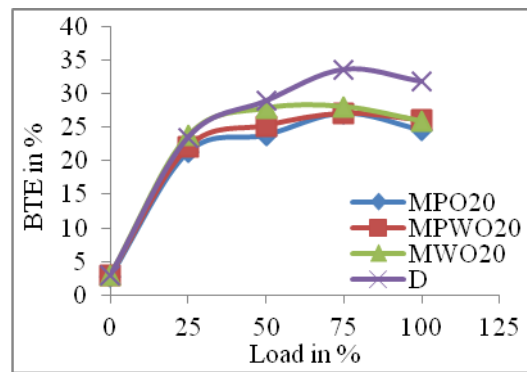

Figure 4.5 Effect of combining MPO and MWO on the BTE of the engine at 20% blending

Figure 4.6 Effect of combining MPO and MWO on the BTE of the engine at 25% blending

Figure 4.7 Effect of combining MPO and MWO on the BTE of the engine at 30% blending

Adding ethanol and acetone to the RPO blends has improved the engine's efficiency compared to biodiesel blends. Figures 4.8 to 4.13 shows the variational plot of load versus the BTE of the engine for various blends of raw biodiesel and ethanol acetone and additions. It is observed that the ethanol and acetone addition to the raw biodiesel blends behaves similarly to that of biodiesel blends with variations in engine load. The average reduction in the engine's efficiency of RPO, RPA, and RPE compared to that of the diesel blends is 32.73%, 30.43%, and 26.60%, respectively.

Figure 4.8 Effect of ethanol and acetone addition on the BTE of the engine with 5% blending of RPO

Figure 4.9 Effect of ethanol and acetone addition on the BTE of the engine with 10% blending of RPO

Figure 4.10 Effect of ethanol and acetone addition on the BTE of the engine with 15% blending of RPO

Figure 4.11 Effect of ethanol and acetone addition on the BTE of the engine with 20% blending of RPO

Figure 4.12 Effect of ethanol and acetone addition on the BTE of the engine with 25% blending of RPO

Figure 4.13 Effect of ethanol and acetone addition on the BTE of the engine with 30% blending of RPO

Figures 4.14 to 4.19 show the variational plot of load versus the BTE of the engine for various blends of raw biodiesel and additions of ethanol and acetone. Adding ethanol (Shrivastava et al. 2021) and acetone to the MPO has improved the engine's efficiency compared to MPO biodiesel blends. Also, the ethanol and acetone addition to the raw biodiesel blends is similar to that of biodiesel blends with engine load variations. The average reduction in the engine's efficiency of MPO, MPA, and MPE compared to the diesel blends is 16.06%, 12.95%, and 8.6%, respectively.

Ethanol and acetone additions to the biodiesel blends of MWO have also shown an improvement in engine efficiency compared to biodiesel blends. Figures 4.20 to 4.25 show the plot of load versus BTE of the engine for various biodiesel blends of MWO, ethanol, and acetone additions. Similar behaviour is found with all the samples at each blend of ethanol and acetone (Dhanarasu et al. 2021). An average deviation with the BTE of engine fuelled with MWO, MWA, and MWE is 11.97%, 9.01%, and 5.05% compared to diesel.

Similarly, ethanol and acetone additions to the biodiesel blends of MPWO have also shown an improvement in engine efficiency compared to biodiesel blends. Figures 4.26 to 4.31 show the plot of load versus BTE of the engine for various biodiesel blends of MPWO, ethanol, and acetone additions. Similar behaviour is found with all the samples at each blend of ethanol and acetone. An average deviation with the BTE of engines fuelled with MPWO, MPWA, and MPWE is 13.81%, 12.19%, and 4.03%, respectively, compared to diesel.

Figure 4.22 Effect of ethanol and acetone addition on the BTE of the engine with 15% blending of MWO

Figure 4.23 Effect of ethanol and acetone addition on the BTE of the engine with 20% blending of MWO

Figure 4.24 Effect of ethanol and acetone addition on the BTE of the engine with 25% blending of MWO

Figure 4.25 Effect of ethanol and acetone addition on the BTE of the engines with 30% blending of MWO

Figure 4.26 Effect of ethanol and acetone addition on the BTE of the engine with 5% blending of MPWO

Figure 4.27 Effect of ethanol and acetone addition on the BTE of the engine with 10% blending of MPWO

Figure 4.28 Effect of ethanol and acetone addition on the BTE of the engine with 15% blending of MPWO

Figure 4.29 Effect of ethanol and acetone addition on the BTE of the engine with 20% blending of MPWO

Figure 4.30 Effect of ethanol and acetone addition on the BTE of the engine with 25% blending of MPWO

Figure 4.31 Effect of ethanol and acetone addition on the BTE of the engines with 30% blending of MPWO

It is observed that with an increase in biodiesel blends, the engine's efficiency decreases because of the lower energy content of biodiesel blends. However, the different sources possess varying energy content. However, it is observed that ethanol additions have improved the engine's efficiency (Alesawi and Qubeissi 2019). Similarly, acetone additions have shown a positive effect in increasing the engine's efficiency. With the additions of ethanol (Liaquat et al. 2020) and acetone (Dhanarasu et al. 2021) to the base biodiesel blend, efficiency improvements are achieved, but they remain lesser than the efficiency of diesel.

BTE refers to the ratio of the brake power to the input power. Generally, the maximum thermal efficiency of the engine run using diesel fuel is at 75% of the loading. Efficiency increases with the increase in load percentage. However, adding biodiesel in

blends decreases the engine's efficiency (Datta and Mandal 2016). The present study has also revealed similar observations.

4.1.2. Brake-specific energy consumption

BSEC refers to the energy consumed to produce a unit power output. Generally, energy consumption increases with the blend proportion of biodiesel because of the fuel's lower energy content or lower mass density.

The following figures represent load plots versus the BSEC for all prepared samples. It can be observed that with an increase in load, the BSEC decreases (Pandian 2019). Figure 4.32 illustrates the Effect of adding acetone and ethanol to diesel on the diesel engine's BSEC. The figure shows a favorable effect in reducing the specific energy consumption with ethanol and acetone additions than diesel. It may be because of the higher CV of ethanol and acetone than diesel. The variation in BSEC of the diesel engine due to ethanol and acetone additions is 2.33% and 1.99%, respectively.

Figure 4.32 Effect of ethanol and acetone blended diesel on the BSFC of the engine

Figures 4.33- 4.38 demonstrate the significance of mixing MPO and MWO. Each combination of MPO and MWO improves the BSEC of MPO. When it comes to the BSEC, MPWO ranks higher than MPO. The average improvement of BSEC of MPO achieved as with MPWO is 3.5%.

Figure 4.33 Effect of combining MPO and MWO on the BSEC of the engine at 5% blending

Figure 4.34 Effect of combining MPO and MWO on the BSEC of the engine at 10% blending

Figure 4.35 Effect of combining MPO and MWO on the BSEC of the engine at 15% blending

Figure 4.36 Effect of combining MPO and MWO on the BSEC of the engine at 20% blending

Figure 4.37 Effect of combining MPO and MWO esters on the BSEC of the engine at 25% blending

Figure 4.38 Effect of MPO and MWO on the BSEC of the engine at 30% blending

Compared to base biodiesel blends, the BSEC is better when ethanol and acetone are added to RPO blends. Figures 4.39–4.44 show the load changes concerning the BSEC for different raw biodiesel, ethanol, and acetone blends. It has been seen that adding ethanol and acetone to raw biodiesel blends makes them behave the same way in BSEC as biodiesel blends do when the engine load changes. The average increase in BSEC of RPO, RPA, and RPE compared to diesel is 41.4%, 37.69%, and 31.46%, respectively.

Figure 4.39 Effect of ethanol and acetone addition on the BSEC of the engine with 5% blending of RPO

Figure 4.40 Effect of ethanol and acetone addition on the efficiency of the engine with 10% blending of RPO

Figure 4.41 Effect of ethanol and acetone addition on the BSEC of the engine with 15% blending of RPO

Figure 4.42 Effect of ethanol and acetone addition on the BSEC of the engine with 20% blending of RPO

Figure 4.43 Effect of ethanol and acetone addition on the BSEC of the engine with 25% blending of RPO

Figure 4.44 Effect of ethanol and acetone addition on the BSEC of the engine with 30% blending of RPO

Figures 4.45 to 4.50 show how the load changes with the BSEC of the engine for different mixes of raw biodiesel and additions of ethanol and acetone. Compared to MPO biodiesel blends, the BSEC is better when ethanol and acetone are added to the MPO. The engine enhancement in the BSEC of the MPO, MPA, and MPE are found at 7.66%, 7.69%, and 3.84%, respectively.

Adding ethanol and acetone to biodiesel blends of MWO has also shown that the BSEC of the engine is better than with biodiesel blends alone. Figures 4.51 to 4.56 show the relationship between load and BSEC for different blends of MWO, ethanol, and acetone added to biodiesel. At each mix of ethanol and acetone, all samples behave similarly. The BSEC average deviation for an engine that runs on MWO, MWA, and MWE is 5.13%, 5.22%, and 0.35% higher than diesel, respectively.

Adding ethanol and acetone to biodiesel blends of MPWO has also shown that the engines work better than with biodiesel blends alone. Figures 4.57 to 4.62 show the relationship between engine load and BSEC for different biodiesel blends with MPWO, ethanol, and acetone. At each mix of ethanol and acetone, all samples behave similarly. The average deviation of an engine that runs on MPWO, MPWA, and MPWE is 7.4%, 6.32%, and 0.54% higher than diesel.

Brake-specific energy consumption increase with the increase in biodiesel blends (Wu et al. 2020). This is because biodiesel's lower calorific value and higher viscosity will harm atomization and combustion, increasing BSEC (Sianturi and Fauziyah 2020). Adding ethanol and acetone positively affects the fuel's energy content due to lesser viscosity and higher energy content (Liaquat et al. 2020) than biodiesel blends. A similar observation is found in the present study too. With the increase in biodiesel blends, the BSEC improves upon the additions of ethanol and acetone. However, ethanol shows a better response compared to acetone.

Brake-specific energy consumption increase with the increase in biodiesel blends (Wu et al. 2020). This is because biodiesel's lower calorific value and higher viscosity will harm atomization and combustion, increasing BSEC (Sianturi and Fauziyah 2020). Adding ethanol and acetone positively affects the fuel's energy content due to lesser viscosity and higher energy content (Liaquat et al. 2020) than biodiesel blends. A similar observation is found in the present study too. With the increase in biodiesel blends, the BSEC improves upon the additions of ethanol and acetone. However, ethanol shows a better response compared to acetone.

4.2 Emission parameters

4.2.1 Carbon Monoxide

Emission CO emissions decrease with an increase in biodiesel blending. Alternatively, there is a significant increase in CO₂ and NO_x emissions (Hoekman and Robbins 2012). Due to the addition of biodiesel blends. The CO emission decrease (Xue et al. 2011). The lower carbon content of the biodiesel blends that it reduces CO emissions, and the other reason is the complete combustion of the fuel, where CO is converted to CO₂ (Liaquat et al. 2020) and simultaneously increases the CO₂ emissions in the engine. However, the variation in CO and CO₂ emissions varies with different sources. Ethanol (Datta and Mandal 2016; Heydari et al. 2017) and acetone (Dhanarasu et al. 2021) addition also have shown similar behavior to biodiesel blends.

CO is considered one of the engine cylinder's harmful exhausts due to the engine cylinder's lack of oxygen. Blending biofuels with diesel has shown a positive significance in reducing CO emissions. Generally, the emissions of CO increase with an increase in engine loading. A similar trend is observed in the present study. Blending RPO, MPO, MWO, and MPWO with diesel has reduced CO emissions. The intensity of reduction is found with the increase in the blending ratio. Also, ethanol (Khalife et al.

2017) and acetone offer further reductions in the CO of the engine. Figure 4.63 shows the plot of CO versus Load for D, DE and DA. the average deviation in ethanol and acetone blended CO compared to diesel are 20.91% and 17.64%, respectively.

Figure 4.63 Effect of ethanol and acetone blended diesel on the CO of the engine

Figures 4.64-4.69 show the significance of combining two distinct methyl esters, MPO and MWO. The MPO-fueled engine can be improved by combining MPO and MWO at each blend. Compared to MPO, the average achievement in the CO of MPWO is 4.23%.

Adding ethanol and acetone to RPO blends improved the CO content compared to biodiesel blends. The variational plots of load vs CO for various blends of raw biodiesel, ethanol, and acetone additives are depicted in Figures 4.70 to 4.75. Adding ethanol and acetone to raw biodiesel blends has a similar CO behaviour to that of biodiesel blends under varying engine loads. The improvements in CO due to RPO, RPA, and RPE compared to diesel are 52.75%, 55.11% and 57.47%, respectively.

Figures 4.76 through 4.81 depict the variational plot of load versus the CO of the engine for various blends of raw biodiesel, ethanol, and acetone. Compared to MPO biodiesel blends, adding ethanol (Shrivastava et al. 2021) and acetone to MPO has improved the CO. In addition, adding ethanol and acetone to raw biodiesel blends is comparable to that of biodiesel blends with engine load variations. Compared to the raw biodiesel blends, the improvements in CO of MPO, MPA, and MPE are 35.59%, 33.44% and 35.59%, respectively.

The CO of the engine improved when ethanol and acetone(Dhanarasu et al. 2021) were added to MWO's biodiesel blends compared to biodiesel blends. Figures 4.82 to 4.87 demonstrate the plot of load versus CO for various biodiesel mixes of MWO, ethanol,

and acetone additives. Every sample exhibits the same behaviour at every concentration of ethanol and acetone. For ethanol and acetone-fuelled biodiesel blends, the average divergence with the CO of an engine running on MWO, MWA, and MWE is 32.90%, 39.87%, and 44.57%, respectively.

The CO of the engine has improved when ethanol and acetone have been added to MPWO diesel blends compared to biodiesel blends. Figures 4.88 to 4.93 demonstrate the plot of load versus CO for various biodiesel mixes of MPWO, ethanol, and acetone additives. Every sample exhibits the same behaviour at every concentration of ethanol and acetone. For ethanol and acetone-fuelled biodiesel blends, the average divergence with the CO of an engine running on MPWO, MPWA, and MPWE is 32.90%, 37.01%, and 32.55%, respectively, compared to diesel.

4.2.2 Carbon dioxide

CO₂ is formed due to the complete combustion of fuel in the combustion chamber. Biodiesel fuelled engines generally produce higher carbon dioxide than diesel-fueled engines due to fuel combustion inside the combustion chamber. Also, ethanol and acetone with different fuels have shown higher CO₂ emissions with additions. In the present study, the prepared alternative fuels have also demonstrated increased CO₂ emissions. A plot of Load versus CO₂ is plotted for all three specimens, namely D, DA, and DE, as shown in Figure 4.94. The average deviation in the CO₂ of ethanol and acetone compared to CO₂ due to diesel is 12.77% and 18.06%, respectively.

The importance of combining the two different methyl esters, MPO and MWO, is illustrated in Figures 4.95 to 4.100. The CO₂ of MPO in each mixture is increased by combining it with MWO. Comparing MPWO to MPO, the average CO₂ accomplishment by MPWO is 1.71%.

Figure 4.94 Effect of ethanol and acetone blended diesel on the CO₂ of the engine.

Compared to biodiesel blends, the CO₂ in RPO blends has improved by adding ethanol and acetone. The variational plot of load vs. CO₂ for various blends of unprocessed biodiesel, ethanol, and acetone additives is shown in Figures 4.101 to 4.106. It has shown that the CO₂ behavior of biodiesel blends with varying engine loads and adding ethanol and acetone to raw biodiesel blends are similar. The average CO₂ increments for RPO, RPA, and RPE are 33.69%, 39.62%, and 49.16%, respectively, compared to diesel.

Figures 4.107 to 4.112 show the variational plot of load vs. CO₂ for various blends of raw biodiesel and adding ethanol and acetone. Adding ethanol (Shrivastava et al. 2021) and acetone to the MPO has enhanced the CO₂ compared to MPO biodiesel blends. Additionally, adding ethanol and acetone to the raw biodiesel blends is comparable to that of the biodiesel blends with varying engine loads. The CO₂ enhancements due to MPO, MPA, and MPE are 18.20%, 22.50%, and 28.63%, respectively, compared to diesel.

The CO₂ of the engine has improved when ethanol and acetone are added to MWO's biodiesel blends compared to biodiesel blends. Figures 4.113 to 4.118 demonstrate the plot of load versus CO₂ for various biodiesel mixes of MWO, ethanol, and acetone additives. Every sample exhibits the same behaviour at every concentration of ethanol and acetone. For MWO, acetone, and ethanol-fuelled biodiesel blends, the average divergence with the CO₂ of an engine running on diesel is 11.82%, 35.85%, and 50.10%.

Similarly, ethanol and acetone additives to MPWO's biodiesel blends have increased engine efficiency compared to biodiesel blends. For different biodiesel mixes with MPWO, ethanol, and acetone additives, the engine load is plotted against CO₂ in Figures 4.119 to 4.124. The samples exhibit the same behaviour for each ethanol and acetone mixture. For MWO, MWE and MWA blends, the average deviations with the CO₂ of an engine running on MPWO are 16.79%, 27.28%, and 25.31%.

4.2.3 Unburnt hydrocarbon

Figure 4.125 shows the graph of load versus UHC for D, DA, and DE samples. The average reductions in UHC of DA and DE compared to D are 7.69% and 11.53%, respectively.

Figures 4.126 to 4.131 demonstrate the importance of combining two different methyl esters, MPO and MWO. Combining MWO's UHC in each blend can be improved with MPO. When MPWO and MPO are compared, the average increase in UHC of MPWO is 5.3%. When ethanol and acetone are added to RPO blends, they reduce UHC compared to biodiesel blends. Figures 4.132–4.137 depict a variational plot of load versus UHC for various blends of raw biodiesel, ethanol, and acetone. When ethanol and acetone are added to raw biodiesel blends, the UHC behavior is similar to that of biodiesel blends with variable engine load. Compared to diesel blends, the average UHC reductions of RPO, RPA, and RPE are 45.56%, 48.22%, and 51.10%, respectively.

Figures 4.138–4.143 depict a variational plot of load versus UHC for various biodiesel blends with and without ethanol and acetone additions. When ethanol (Shrivastava et al. 2021) and acetone are added to MPO biodiesel, UHC levels improve compared to MPO biodiesel blends. Furthermore, adding ethanol and acetone to raw biodiesel blends is analogous to adding ethanol and acetone to biodiesel blends with engine load variations. When compared to diesel, UHC reductions are 30.86%, 33.51%, and 39.37%

Compared to biodiesel blends, ethanol, and acetone (Dhanarasu et al. 2021), additions to MWO biodiesel improved engine UHC. Figures 4.144- 4.149 show plots of load versus UHC for various biodiesel blends containing MWO, ethanol, and acetone additions to MWO. All of the samples behave similarly at each ethanol/acetone blend. The average UHC deviation of an MWO, MWA, and MWE compared to diesel are 24.81%, 34.09%, and 39.85%, respectively.

Similarly, adding ethanol and acetone to MPWO biodiesel increased engine efficiency compared to biodiesel blends. Figures 4.150-4.155 show the engine's load versus UHC plot for various MPWO, ethanol, and acetone biodiesel blends. At each ethanol/acetone blend, all of the samples behave similarly. For ethanol and acetone-fueled biodiesel blends, the average deviation with UHC of an MPWO-fueled engine is 27.17%, 38.65%, and 37.71%, respectively.

Figure 4.152 Effect of ethanol and acetone addition on the UHC of the engine with 15% blending of MPWO

Figure 4.153 Effect of ethanol and acetone addition on the UHC of the engine with 20% blending of MPWO

Figure 4.154 Effect of ethanol and acetone addition on the UHC of the engine with 25% blending of MPWO

Figure 4.155 Effect of ethanol and acetone addition on the UHC of the engines with 30% blending of MPWO

UHC emissions decrease with increased biodiesel blending (Petersen et al. 2018). A sample can emit less UHC only if a complete combustion process exists. Due to excess oxygen in the blended samples compared to diesel, the combustion process emits less UHC (Ogunkunle and Ahmed 2021). Similar observations in the trend are also found with the base biodiesel blends. The addition of ethanol and acetone (Dhanarasu et al. 2021) has also contributed to the reduction in the UHC; the reason behind this is the oxygen supply during combustion. However, ethanol can reduce UHC emissions better as compared to acetone.

Gaseous hydrocarbons are found in the relatively thick low-temperature boundary layer along the cylinder wall, and the apertures are the leading cause of hydrocarbon emissions. Generally, the addition of biodiesel reduces UHC emissions. Further addition of acetone and ethanol (Khalife et al. 2017) reduces UHC emissions.

4.2.4 Nitrous oxide

Figure 4.156 shows the graph of load versus NO_x for D, DA, and DE samples. The average reductions in NO_x of DA and DE (Khalife et al. 2017) compared to D are 35.34% and 43.75%, respectively.

Figures 4.157-4.162 demonstrate the importance of combining two different methyl esters, MPO and MWO. NO_x of MPO in each blend can be improved by combining it with MWO. When MPWO and MPO are compared, the average NO_x achievement is 9.74%.

When ethanol and acetone are added to RPO blends, they reduce NO_x compared to biodiesel blends. Figures 4.163-4.168 depict a variational plot of load versus NO_x for

various raw biodiesel, ethanol, and acetone blends. When ethanol and acetone are added to raw biodiesel blends, the NO_x behaviour is similar to that of biodiesel blends with variable engine load. Compared to raw biodiesel blends, NO_x reductions are 144.05%, 163.97%, and 172.68%, respectively.

Figures 4.169–4.174 depict a variational plot of NO_x for various raw biodiesel blends with and without ethanol and acetone additions. When ethanol (Nair et al. 2021) and acetone are added to MPO biodiesel, NO_x levels improve compared to MPO biodiesel blends. Furthermore, adding ethanol and acetone to raw biodiesel blends is analogous to adding ethanol and acetone to biodiesel blends with engine load variations. Unlike diesel blends, NO_x reductions of MPO, MPA, and MPE are 107.90%, 117.39%, and 122.45%, respectively. Compared to biodiesel blends, ethanol, and acetone.

Compared to biodiesel blends, ethanol and acetone additions to MWO biodiesel improved engine NO_x. Figures 4.175-4.180 show load versus NO_x plots for various biodiesel blends containing MWO, ethanol, and acetone. All of the samples behave similarly at each ethanol/acetone blend. The average NO_x deviation of an MWO, MWA, and MWE-powered engine compared to diesel is 77.4%, 86.27%, and 98.21%, respectively.

Similarly, adding ethanol and acetone to MPWO biodiesel increased engine efficiency compared to biodiesel blends. Figures 4.181-4.186 show the engine's load versus NO_x plot for various MPWO, ethanol, and acetone biodiesel blends. At each ethanol/acetone blend, all of the samples behave similarly. The average deviation with NO_x compared to diesel for MPWO, MPWA, and MPWE-powered engines is 93.03%, 98.45%, and 99.25%, respectively.

Figure 4.185 Effect of ethanol and acetone addition on the NO_x of the engine with 25% blending of MPWO

Figure 4.186 Effect of ethanol and acetone addition on the NO_x of the engines with 30% blending of MPWO

NO_x emissions increase with an increase in the blend percentage of biodiesel. Oxygen in biodiesel fuel results in increased heat release during combustion, which significantly

contributes to increased NO_x emissions (Palash et al. 2013). incremental ethanol additions have also shown NO_x increments (Datta and Mandal 2016; Maleney et al. 2017). The increment is because it adds oxygen content to the fuel, increasing the combustion temperature and resulting in higher NO_x. The addition of acetone shows similar behaviour (Dhanarasu et al. 2021).

CHAPTER 5

STATISTICAL ANALYSIS OF PERFORMANCE AND EMISSIONS OF THE ENGINE

5.1 Analysis of variance (ANOVA) analysis and Multi Linear Regression Modelling

An ANOVA test is a way to find out if survey or experiment results are significant. In other words, they help you to figure out if you need to reject the null hypothesis or accept the alternate hypothesis .

ANOVA and MLRM are carried out to predict the engine's performance and emission parameters. The input parameters considered for this study are blend percentage (B), load (L), the mass of fuel consumed (MF), density (D), kinematic viscosity (KV) and calorific value (CV) of the fuel. A higher order model is developed to improve the model's accuracy. The cross-products considered are load- mass of fuel consumed and blend-mass of fuel consumed. The prediction models are developed at a confidence interval of 95%. Minitab V19 is used to carry out ANOVA analysis and MLR modelling.

The models that are developed performance is rated based on their R- square values. It is found that the R-squared values in predicting all the parameters are above 70%. The Most significant parameter contributing to the output variable's variation is decided based on the P- Values (≤ 0.05). ANOVA analysis is tabulated, and the significant parameters are identified based on the P-Values. The contribution of each parameter in the development of the model is also represented in the form of a pie chart.

A regression equation and performance and the effect of each parameter are described under the regression analysis. The T-value signifies the Effect of the parameter. The performance of the model is described based on the R-squared value. A graph of Predicted versus experimental is drawn for each output. A regression model is also developed to predict the predicted value based on the experimental value.

5.1.1 ANOVA analysis for the BTE of the Engine

Table 5.1 represents the results of the ANOVA analysis for BTE. All the input parameters are significant, with P-values less than 0.05, except for KV. Figure 5.1

shows that the most influential parameter for BTE is load, followed by the mass of fuel consumed, whose contributions are 61.22% and 25%.

5.1.7 Development of regression model to predict the BTE of engine

A regression equation and performance and the Effect of each parameter are described under the regression analysis. The T-value signifies the Effect of the parameter. The performance of the model is described based on the R-squared value. A graph of Predicted versus experimental is drawn for each output. A Regression model is also developed to predict the predicted value based on the experimental value and shown in Figures 5.7 to 5.12.

The regression model is developed to predict the BTE of the engine and is represented as Equation 5.1.

$$\text{BTE (\%)} = 10.6 - 0.2786B + 0.6907L + 36.16D + 1.34 \text{ KV} - 0.619\text{CV} - 100784\text{MF} + 969B \text{ in \%} * \text{MF} - 399L * \text{MF} \dots\dots\dots (5.1)$$

Where, BTE is Brake thermal efficiency in % B is blending in %, L is Load in %, D is Density in g/cc, KV is kinematic viscosity in Cst, CV is calorific value in MJ/Kg, MF is mass of fuel consumed in Kg/s

Table 5.7 shows the performance of the regression model developed. The model's performance is around 94.17% in predicting the BTE of the engine. From Table 5.8, it is clear that the T-values of B, CV, and MF have negative correlations in the development of the model. The other parameters, P, D, and KV correlate positively. Figure 5.7 illustrates the plots of predicted BTE versus experimental BTE.

Table 5.7 Model summary for predicting the BTE of the engine

CHAPTER 6

ANN ANALYSIS OF THE PERFORMANCE AND EMISSIONS OF THE ENGINE

6.1 Introduction

A deep learning method, the Artificial Neural Network (ANN), arose from the concept of biological neural networks in human brains. ANN is developed due to an effort to replicate the workings of the human brain. Biological neural networks have many similarities to ANNs. However, ANNs operate somewhat differently. ANN has three layers: the input layer, the output layer, and the hidden layer or layers. The nodes in the input layer must be connected to the nodes in the hidden layer. Each node in the hidden layer must be connected to the nodes in the output layer. The Learning and training methods are used to compute the ANN model's operations, including data collection and analysis, network structure design, number of hidden layers, network simulation, and trade-offs between weights and bias.

6.2 Multi-Layer Perceptron Neural Network (MLPNN)

In this study, an MLPNN model, a feed-forward-back propagation artificial neural network, is used to predict the performance and emission parameters of the engine. The structure of the model consists of three layers an input layer (M_i), an output layer (O_i), and a hidden layer (H_i).

As shown in Figure 6.1, the (M_i) enters the feed-forward neural network where each M_i is connected with a weight(W_i) as a product in the training process. The product is then summed into a junction with a bias(B_j) represented as Eq.. 6.1. The present investigation's input parameters are a blend, load, density, kinematic viscosity, and calorific value. The output parameters include BTE, BSEC, CO, CO₂, UHC, and NOX (Hosamani et al. 2021).

$$X = \sum_{i=1}^n (W_{ij}M_i) + b_j \dots \dots \dots (6.1)$$

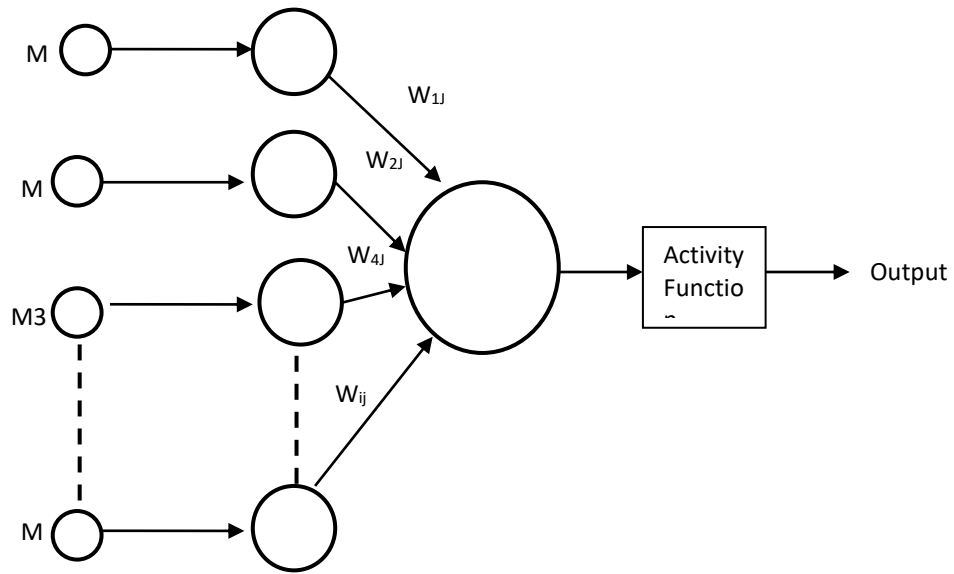

Figure 6.1: Generalized structure of artificial neurons

Two transfer functions are used, one LOGSIG and the other TRANSIG. TRANSIG is the most commonly used function. The activation function used is the sigmoid function and is represented as shown in Eq.. 6.2

$$F(X) = 1/(1+ e^{-x})..... (6.2)$$

During the training and testing period, the input and the target data enter into the network. The inputted data are trained by learning algorithms, which most commonly used is the Levenberg-Marquardt (LM) (Hagan and Menhaj 1994), which is faster than other algorithms. For performing the analysis, MatLab 2019a is used.

6.3 Development of ANN models for predicting the performance and emissions of the engine

A total of 375 samples are used to carry out the analysis. An MLPNN model is chosen, including six input and six output parameters. Input parameters include blend, engine load, the mass of fuel consumed, density, kinematic viscosity, and calorific value. The output parameters are BTE, BSEC, CO, CO₂, UHC, and NO_x.

Of 375 data sets, 263 are used for training the model, and the remaining 112 are used for testing and validating the model. 50% of 112 data is shared equally for each testing and validation. A feed-forward backpropagation algorithm is used as a learning algorithm. Based on the trial and error techniques, the neurons are chosen from 4-10 (Kannan 2013). The TRANSIG transfer function is used as a sigmoid function.

The output and the error involved in the development of the model are recorded. The root mean square error is then computed for each neuron. The best model is the neuron corresponding to the least RMSE value (Kumar 2020). The equation to compute RMSE is

represented as Eq.. 6.3. The RMSE is calculated for each neuron, varying from 4 to 10 in increments of one. It is found that the optimized model for predicting BTE, BSEC, CO, and NO_x is the one with 6-neurons. The best model for predicting the UHC and CO₂ is the one with 5 neurons. The details of the RMSE values for the output parameters with different neurons are given in Table 6.1

Table 6.1 RMSE of the output parameters for various neurons

Neurons	RMSE					
	BTE	BSEC	CO	CO2	UHC	NOX
4	10.6712	0.65102	0.29439	8.89302	6.39242	29.162
5	4.71505	0.53651	0.46011	1.06747	3.84756	25.1842
6	3.61402	0.4749	0.26433	1.44179	3.8746	5.01839
7	4.03607	0.55427	0.42545	1.21049	4.02336	23.0194
8	18.4185	1.13339	0.77433	3.36957	4.25555	28.8222
9	4.25471	1.21866	0.4881	1.6492	4.17979	26.2116
10	3.69299	0.51741	0.27585	1.07327	4.14955	24.8236

The performance model and regression fittings for both 5 and 6 neurons are shown in Figures 6.2 to 6.9. Figures 6.2 and 6.6 represent the MLPNN model's architecture with several 6 and 5 neurons inputs. A screenshot of the training state can be visualised in Figures 6.3 and 6.10, where the number of validations checks and the epoch shall be noted. Once the network is trained, the performance check is carried out. Figures 6.4 and 6.11 show the validation performance for 6 and 5 neurons. The best validation is represented at epoch 5, which is 110.7545 for a 5-neuron model.

Similarly, a validation at an epoch which is 992.4 is found for a 6- neuron model. The regression model in Figures 13 and 17 shows the pattern of data fitting for the model in terms of R-Square. The R-squared value for the model developed is 0.99 for both 6 and 5 neurons ANN models. The performance of the regression models is shown in Figures 40 and 44.

Figure 6.2 Network architecture of MLPNN with 5 neurons

Figure 6.3 Pictorial view of the training state with 6 neurons

Figure 6.4 Performance of ANN training and testing with 6 neurons

Figure 6.5 Regression Model of MLPNN with 6 neurons

Figure 6.10 shows the architecture of the MLPNN model with a number of inputs of 6 and the number of neurons of 6. The output variables are also 6. A screenshot of the training state can be visualized in Figure 6.11, where the number of validation checks and the epoch shall be noted. Once the network is trained, the performance check is carried out. Figure 6.12 shows the validation performance for 6 neurons. The best validation is represented at epoch 19, which is 142.8933. the regression model, as shown in Figure 6.13, shows the pattern of data fitting for the model in terms of R-Square. The R-squared value for the model developed is 0.99344, 0.99113, 0.99022, and 0.9926 for training, validation testing, and overall fitting with 6 input neurons.

Figure 6.7 Pictorial view of the training state with 6 neurons

Figure 6.8: Performance of ANN training and testing with 6 neurons

Figure 6.9 Regression Model of MLPNN with 6 neurons

Plotting an error analysis is a standard mode of validating the model's performance. A similar thing is achieved in this study. Errors are measured as the difference between the experimental and predicted values. These errors are represented in the form of a bar graph. A random distribution of the bars on either side of the zero line indicated the best validations of the model. Figure 6.10 to 6.15 shows the Error plot for BTE, BSEC, CO, CO₂, UHC, and NO_x. The error bars show a random distribution of the data on either side of the zero line. Hence the model can be considered to be validated.

CHAPTER 7

FIELD STUDY USING ALTERNATIVE FUELS

7.1 Introduction

In the present study, attention is given that the study is not limited to only experimentations on the lab scale. Hence, the same application is also extended to the case study. Mine environment plays a vital role in the sustainability of every mine, as per the web report “clean cities,” June 2009. It is reported that using biodiesel in underground mines reduces the particulate matter and hence be implemented. The case study is carried out in one of southern India's esteemed underground metal mines.

7.2 About the case study mine

Hutti Gold Mines Ltd. (HGML) is the only producer of primary gold in the nation, a Government of Karnataka undertaking founded in 1947 as Hyderabad Gold Mines. Gold reserves in Karnataka have been actively explored, developed, and exploited by HGML. The company has its corporate headquarters in Bangalore. It runs two mining operations: the Hutti Gold Unit (HGU) in Raichur district and the Chitradurga Gold Unit (CGU) in Chitradurga district, both of which have active mines in Ajjanahalli (Tumkur District). HGU is a fully integrated facility with an annual production capacity of 5,50,000 tonnes.

7.3 Application of alternative fuels on the equipment used in underground mines

The Indian regulation for blending biodiesel guides the application of alternative fuels. As per the Indian biofuel policy regulations, it must blend 20% of biodiesel with diesel. The study also intends to implement a 20% blending of the basic biodiesel fuels with diesel, i.e., MPO, MWO, and MWCO. However, ethanol and acetone blendings are not covered because of the challenges faced with fuel line systems. Hence a 20% blending of RPO, MPO, MWO, and MPWO is tested on the underground mine equipment. The equipment provided by the mining authority was a TATA make tipper of BS-III engine purchased in 2007 by the mine. The same vehicle was used to test all the samples. The vehicle was used to shift the OB from the mine.

The measurement included four gases: CO, Nitric oxide (NO), nitrogen dioxide (NO₂), and NO_x oxides of nitrogen. The emission equipment used for the study is Drager EM

200 E. The pictorial representation of the same is shown in Figure 7.1. The specifications of the equipment are listed in Table 7.1.

Figure 7.1 Pictorial representation of Dräger EM 200 emission measuring equipment (Courtesy of Dräger)

Table 7.1 Specifications of the Dräger EM 200 exhaust analyser

Display		Liquid crystal graphic display, backlit, manual		
Interface		USB for PC interface, infrared for printer, no multifunction jack for additional instruments		
Operating temperature		+5 °C ... +40 °C		
Power supply		Internal: high power battery, 4.8 V 2,000 mAh, an indication of the state of charge, external charger		
Operating capacity		Typically 10 hours		
Gas extraction		Membrane pump for gas sampling		
Weighting		1,100 g		
Dimensions		195 mm x 165 mm x 75 mm (H x W x D)		
Display	Principle of measurement	Measuring range (PPM)	Resolution Accuracy (PPM)	Accuracy (PPM)
CO	EI chem Sensor	0-8000	1	Up to±100PPM
NO		0-2000		Up to±10PPM
NO ₂		0-200		Up to±5PPM
NOX		0-2000		Up to±10PPM

Experimental trials are conducted using the base biodiesel samples of 20% blendings, i.e., the blends of MPO, MPWO, MWO, and RPO 20% and 80% of diesel by volume. The experiments are conducted on a TATA tipper truck which is a 2007 make BSIII engine. It is observed that CO can be reduced with the implementation of biodiesel. Alternatively, the number of NO_x increased.

7.4 Emission Testing for the Use of alternative fuels

The fuel samples are subjected to combustion in the tipper, and the emission values, namely CO, NO, NO₂, and NO_x, are recorded. Following Table 7.2 illustrate the representation of the emission values at empty load conditions and full load conditions:

Table 7.2 Results of the emissions of various fuels used at empty load condition and full load conditions

Type of Emissions	Empty load condition				
	Diesel	MPO	MWO	MPWO	RPO
CO (PPM)	61	58	51	55	43
NO (PPM)	267	296	287	291	320
NO ₂ (PPM)	26	33	24	28	36
NO _x (PPM)	293	329	311	299	356
Full load condition					
CO (PPM)	601	318	300	308	296
NO (PPM)	67	89	75	82	96
NO ₂ (PPM)	36	37	31	35	41
NO _x (PPM)	103	126	106	117	137

The deviation measures in CO, NO, NO₂, and NO_x compared to diesel are estimated for both idle and high idle conditions. Table 7.3 illustrates the MPO, MWO, MPWO, and RPO deviations. The largest deviation is found in the RPO blend for CO and NO_x emissions. RPO is considered a good carbon reducer. Alternatively, increasing the nitrogen oxide emissions.

Table 7.3 Estimation of deviations of emissions of biodiesel blend from diesel.

	Deviations with respect to diesel			
Type of Emissions	Empty load condition			
	MPO	MWO	MPWO	RPO
CO (PPM)	4.918033	16.39344	9.836066	29.5082
NO (PPM)	-10.8614	-7.49064	-8.98876	-19.8502
NO ₂ (PPM)	-26.9231	-7.69231	-11.5385	-38.4615
NO _x (PPM)	4.918033	16.39344	9.836066	29.5082
	Full load condition			
CO (PPM)	47.08819	50.08319	48.75208	50.74875
NO (PPM)	-32.8358	-11.9403	-22.3881	-43.2836
NO ₂ (PPM)	-2.77778	13.88889	2.777778	-13.8889
NO _x (PPM)	-22.3301	-2.91262	-13.5922	-33.0097

CHAPTER 8

CONCLUSIONS

8.1 Summary of the study

In the present study, different forms of alternative fuels are developed, with *Pongamia pinnata* as a basic resource. These include raw form, esterification form, and combinational with other methyl esters. Further, the significance of adding ethanol and acetone to the samples is also studied. The samples are subjected to combustion in an IC engine at the laboratory. The performance and emission parameters are evaluated. The Effect of loading and blending are studied. Statistical analysis is carried out, and ANN models are developed to predict the performance and emission parameters of the engine. A field study on the air quality parameters of mine equipment is carried out by implementing the base biodiesel blends as per Indian biofuel regulations(20% blending). The conclusions and observations are as follows

8.1.1 Properties of the samples

- Mixing methyl esters of waste cooking oil (MWO) with methyl esters of *Pongamia pinnata* oil (MPO) improved the properties of MPO.
- A 10% blending of ethanol and acetone to MPO, MWO, MPWO, and Raw *Pongamia* Oil (RPO) along with diesel improved the Calorific value (CV), kinematic viscosity (KV), and density.
- The properties of all studied samples are found to be much closer to the properties of diesel. However, ethanol tends to improve higher as compared to acetone. DE is considered the best alternative with properties.
- The maximum deviation in the properties with emulsifications for density, kinematic viscosity, and calorific value is with RPO, which is 1.66% higher, 13.24% higher, and 1.81% lower at the highest blend of 30%, respectively. Hence, RPO is considered the poorest fuel source as far as the properties are concerned.

8.1.2 Engine test

- The engine test reveals that mixing two methyl esters, namely, MPO and MWO, improves the quality in terms of engine performance and emissions compared to individual sources.

- A 10% addition of acetone and ethanol has shown positive improvements in the efficiencies and emissions. However, the performance and emission deteriorate with increased biodiesel blends.
- There is a decrease in the efficiency of the engine fuelled with RPO. RPO is the poorest source compared to diesel, with an efficiency deviation of 32.73% at a maximum blend of 30%.
- The BSEC of blended samples increases with biodiesel blends. The average deviation of RPO with diesel is 41.4% from diesel.
- CO decreases with an increase in blend percentage. The maximum reduction in CO is obtained for RPE compared to diesel. The maximum deviation is found to be 57.47%, respectively, at 30% blending.
- CO₂ increases with biodiesel blends. The increase in CO₂ is higher for RPE. Diesel is considered the better source in the reduction of CO₂. The average deviation of UHC is 49.16% at 30% blending.
- UHC increases with an increase in biodiesel blending. The decrease in UHC is found for RPE. Diesel is considered the better source in the reduction of UHC. The average deviation of UHC compared to diesel is 51.10% at 30% blending.
- NO_x increase with biodiesel blends the reduction in NO_x is higher for RPE. Diesel is considered the better source in the reduction of NO_x. The increase in NO_x is found to be 172.68% at 30% blending.

8.1.3 Statistical analysis

- ANOVA and regression analysis are carried out using Minitab V 19. The results reveal that the developed models' performance is good, with an R-square value of more than 70%. Load and blend are considered the most significant parameters in predicting the performance and emissions of the engine.
- Equations for predicting the performance and emission parameters are listed under section 5.2. A graph of experimental and predicted values is plotted to identify the relationship between experimental values and predicted values.

8.1.4 ANN Modelling

- ANN modeling using MatLab 2019a is carried out using an MLPNN network. The trial and error approach is used. The number of neurons are varied from 4 to

10 in increments of 1. The performance, output, and error for each neuron are recorded. The RMSE is computed. The models' performance is judged based on the least R-square value.

- It is found that the optimised model for predicting BTE, BSEC, CO, and NO_x is the one with 6 neurons. The best model for predicting the UHC and CO₂ is the one with 5 neurons.

8.6 Field study

- Samples MPO, MWO, MPWO, and RPO with 20% blending are subjected to fuelling in a TATA make tipper. The observations revealed that the tipper's CO emission was reduced. But nitrogen oxides increase (NO, NO₂, and NO_x) in every form. The best reducer of CO emission is RPO, with deviations of 29.5% and 50.74% with diesel at both idle and high idle conditions, respectively. RPO increases NO_x emissions. The deviations measured are 29.5% and 33%, respectively.

8.7 Scope for future work

- Dimensional analysis of the model to the prototype of lab scale engine with industrial tipper.
- Design and develop fuel filters, especially for biodiesel blends.
- Corrosive study of different metals subjected to biodiesel applications.

List of Publications based on Ph.D. Research Work

Sl. No.	Title of the paper	Authors (In the same order as in the paper. Underline the Research Scholar's name)	Name of the Journal/ Conference/ Symposium, Vol., No., Pages	Month & Year of Publications	Category *
1	A Comparative Study and Regression Analysis on Physico-Thermal Properties using Pongamia Pinnata-Waste Cooking Oil Methyl Ester Mixture	Balaji Rao K, B. M. Kunar, Ch. S. N. Murthy	Energy Sources, Part A: Recovery, Utilization, and Environmental Effects Vol. 1, 1-12 (Scopus)	May 2021	1
2	A Critical Review on Different Biodiesel Blends and their Application in Underground Mining Machineries	Balaji Rao K, B. M. Kunar, Ch. S. N. Murthy	International Conference on Recent Trends in Technology, Engineering and Applied Science (ICRTTEAS 2019),	12th to 13th April 2019.	4
3	A Comparative Assessment and Statistical Analysis of Performance and Emissions of Diesel Engine Fuelled with Emulsified Methyl Esters of Pongamia Pinnata diesel blends	Balaji Rao K, B. M. Kunar, Ch. S. N. Murthy	Advances in Energy, Environment for Sustainable Development-2022	07-08 January, 2022	4
4	Statistical Analysis and Comparative Assessment on the Performance and Emissions of a Diesel Engine Fuelled using Diesel-Ethanol and Diesel-Acetone Blends	Balaji Rao K, B. M. Kunar, Ch. S. N. Murthy	Environmental Quality Management	Communicated	1

*Category: 1: Journal paper, full paper reviewed 2: Journal paper, Abstract reviews 3: Conference/Symposium paper, full paper reviewed
4: Conference/Symposium paper, abstract reviewed 5: Others (including papers in Workshops, NITK Research Bulletins, Short notes etc.)
(If the paper has been accepted for publication but yet to be published, the supporting documents must be attached.)

B.R.K.
Balaji Rao K
Research Scholar

B.M.K. & C.S.N.M.
Dr. B. M. Kunar & Prof. Ch. S. N. Murthy (Retd.)
Research Guides

BIODATA

- 1. Name** : Balaji Rao K
2. Father's Name : Krishna Murthy K
3. Mather's Name : Vimala Bai K
3. Date of Birth : 01-05-1983
4. Nationality : Indian
5. Marital Status : Married
6. Present Position : Research Scholar, NITK, Surathkal
7. Address for Communication : # 2429, 1st Main, 3A cross,
 Vivekanandnagar, Bangarpet, Kolar (DT),
8. Mobile : (+91)-9483774273
9. E-mail : balajiada@gmail.com
10. Academic Qualifications:

Degree	Specialization	Year	College	University	%/CGPA
M. Tech (Full Time)	Engineering Design	2012- 2015	Er. Perumal Manimekalai College of Engineering and Technology, Hosur	Anna University, Chennai	7.35 (CGPA)
B. E (Full Time)	Mechanical Engineering	2002- 2006	Bangalore College of Engineering and Technology, Bangalore	Visveswaraya Technological University, Belgaum	63.11%

11. Work Experience: (7 Years)

From	To	Designation	Organization
June 2015	Dec 2017	Assistant Professor (Mechanical Engg.)	Dr. T. Thimmaiah Institute of Technology, Karnataka
Sep 2009	June 2012	Lecturer (Mechanical Engg.)	Dr. T. Thimmaiah Institute of Technology, Karnataka
Apr 2008	Sep 2009	Consultant Engineer	Aeronautical Development Agency, Bangalore
Mar 2007	Dec 2007	Lecturer (Mechanical Engg.)	CMR institute of Technology, Bangalore
